Helping People Write:
Grammar Checking and Beyond

Robert Dale
Centre for Language Technology
Macquarie University
What This Course is About

• How we can use NLP tools and techniques to help people write:
  – Spell checking
  – Grammar checking
  – Style checking and discourse-level assistance
• These materials, along with a bibliography, are available at:
What This Course is Not About

- Teaching or helping with handwriting
- Teaching how to type
- Teaching a language
- Productivity tools like editors and word processors
Overview

- Introduction: The Need
- Spell Checking
- Grammar Checking
- Helping Non-Native Speakers
- Beyond Spelling and Grammar Checking
- Conclusions
Common Errors in English
Ways of Categorising Errors

• By symptom:
  – Misspelled words
  – Ungrammatical sentences
  – Stylistic disfluencies and inconsistencies

• By cause:
  – Mechanical errors [also known as errors of execution or performance errors]
  – Cognitive errors [also known as errors of intention or competence errors]
An Analysis of Student Writing Errors

• Connors and Lunsford 1988:
  – 21,500 corrected student papers from 300 teachers across the USA
  – 30% typed, 70% handwritten
  – Length varied from less than a page to over 20 pages
  – Randomly selected 3000 for analysis
A Taxonomy of Errors

- Developed on the basis of an analysis of 300 papers

</table>
Some Examples

- **Comma splice:**
  - It is nearly noon, we must stop for food.

- **No comma in non-restrictive phrase:**
  - The man who I knew well was unhappy.

- **Unnecessary comma with restrictive phrase:**
  - The man, who I knew well, was unhappy.

- **Dangling or misplaced modifier:**
  - Turning the corner, a handsome school building appeared.

</tbody>
</table>
Prevailing Findings

• A large proportion of errors are very simple
• The nature of the errors to be dealt with depend on the context of writing production:
  – Non-native speakers
  – Authored text being copyedited
  – Technical manuals
  – Translations
• But: complex errors may be ignored or considered out of scope
Complex Errors

• The living area is something you would expect to find in a house, let alone an apartment.

• If there are mistakes to be acknowledged, we will not shy away from doing so.

• How can one write a minimal manual, not as a cut-down version of a conventional manual, but derived from first principles of what users need successfully to start up their use of a system, and to provide the basis of their subsequent learning of it?
Conclusions

• Many problems in writing are what we might think of as ‘low level’ errors: spelling, punctuation, typographic mistakes . . .

• . . . but many problems in real texts are at a higher level than straightforward textbook grammar errors
Overview

• Introduction: The Need
• Spell Checking
• Grammar Checking
• Helping Non-Native Speakers
• Beyond Spelling and Grammar Checking
• Conclusions
Spell Checking

• What’s a Spelling Error?
• Non-Word Error Detection
• Error Correction
• Real-Word Error Detection
What is a Spelling Error?

• How many spelling errors are there here?
  – *Wot* color is the *dawg*?
  – *C u l8er*

• A definition:
  – A spelling error is a word which is not spelled as it should be
Use Cases for Spell Checking

• Correcting spelling errors in text
• Fixing OCR output
• Correcting spelling errors in search queries
• Some solutions allow interaction, others require machine autonomy
Spell Checking

• What’s a Spelling Error?
• Non-Word Error Detection
• Error Correction
• Real-Word Error Detection
Non-Word Errors vs Real-Word Errors

• The boys ate thier toast.
• The boys ate there toast.
Unix Spell

$ spell
This is the storry abuot an event that went from baad to wurse
abuot
baad
storry
wurse
$
Storage Issues

1981: The original PC's maximum memory using IBM parts was 256 KB: 64 KB on the motherboard and three 64 KB expansion cards.

A word list of 100k words occupies around 500KB.
Peterson’s Three Levels of Storage

• Small dictionary of frequently used words [100–200 words]
• Document-specific words [1000–2000 words]
• Larger secondary storage [10k–100k words]
Dictionary Storage via Tries
Problems with Word Lists

• False Negatives
  – A misspelled word may not be flagged as a spelling error because it is orthographically identical to some other valid word

• False Positives
  – A valid word may be flagged as a spelling error because it is not in the list
Spell Checking

- What’s a Spelling Error?
- Non-Word Error Detection
- Error Correction
- Real-Word Error Detection
The Task

- Given a word which is assumed to be misspelled, find the word that the author intended to type
Spell Checking

- Detect Error
- Generate Candidate Corrections
- Rank Candidates
Interactive Correction with Candidates

This is not the bast...
Finding Candidate Corrections

• Look for ‘nearby’ real words
• Edit distance:
  – An edit = a deletion, an insertion, a transposition or a substitution
  – Each edit adds 1 to the edit distance between strings
• Damerau 1980: 80% of spelling errors are 1 edit from the correct string
Edit Distance

- **Deletion:**
  - continuous → continuous

- **Insertion:**
  - explanation → explanation

- **Substitution**
  - anyboby → anybody

- **Transposition:**
  - autoamtically → automatically
Using Edit Distance

• For a hypothesized misspelled word:
  – Generate all strings within an edit distance of 1
  – Filter non-words out of the list

  teh   →   tea   →   tea
  teb   →   teb
  ...   →   ...
  the   →   the
Potential Problems with Edit Distance

• For a string of $n$ characters from an alphabet of size $k$, number of strings within edit distance 1:
  $$k(2n + 1) + n - 1$$

• Peterson [1980]: an average of 200 dictionary accesses for each misspelling

• Also: words > edit distance 1 are ignored
Approaches to Spelling Correction

- Yannakoudakis and Fawthrop [1983]: Error Patterns
- Kernighan, Church and Gale [1990]: The Noisy Channel Model
- Agirre et al [1998]: Using Context
- Brill and Moore [2000]: String-to-String Edits
- Toutanova and Moore [2002]: Pronunciation Modeling
What Causes Spelling Errors?

- Typing errors (typographic errors, errors of execution)
  - the → teh
  - spell → speel

- Cognitive errors (orthographic errors, errors of intention)
  - receive → recieve
  - conspiracy → conspiricy
  - abyss → abiss
  - naturally → nacherly
Yannakoudakis and Fawthrop [1983]: Error Patterns

- Problem Statement:
  - Given a non-word error, generate a ranked list of candidate replacements based on common error patterns
- Background assumption:
  - Many errors are due to phonetic confusion
  - But conversion into a phonetic coding assumes a dialect
Yannakoudakis and Fawthrop [1983]: The Approach

- Analysed a corpus of 1377 spelling errors
- **Divide each word into spelling elements** — a bit like vowel and consonant clusters, but oriented towards typical confusions in spelling:
  - F-OR-EI-GN
  - D-I-PH-TH-ER-IA
  - F-A-V-OUR-A-B-L-E
Yannakoudakis and Fawthrop [1983]: Error Rules

- A ‘vocabulary’ of 299 spelling elements
- Very large space of possible element-to-element replacements
- Constrained by observed patterns:
  - Doubling or singling of characters
  - Errors involving specific characters
  - Errors involving related phonemes
  - …
  - → 3079 error rules
Yannakoudakis and Fawthrop [1983]:
Other Heuristics

- The most frequent length of an error form is one character less than the dictionary form.
- Typing errors are caused by hitting an adjacent key to the one intended or by hitting the correct key and its neighbour.
- Short error forms do not contain more than one error.
- If the error form is short, only dictionary words differing in length by one character from the error form are examined.
Yannakoudakis and Fawthrop [1983]: Examples

- F-ILIPIN-OE-S → PH-ILIPIN-O-S
- CA-PH-EINE → CA-FF-EINE
- When there’s more than one possible correction, choice is made via ‘subjective Bayesian probabilities’ on the dictionary words and the error rules
Yannakoudakis and Fawthrop [1983]: Performance

- Corrected 90% of 1153 error forms
  - In 95% of these corrections one word was identified
  - In 5% a choice of between 2 and 4 words was offered
- Mean time to correct an error was 22 seconds, with a minimum of five seconds and a maximum of 50 seconds
Approaches to Spelling Correction

- Yannakoudakis and Fawthrop [1983]: Error Patterns
- Kernighan, Church and Gale [1990]: The Noisy Channel Model
- Agirre et al [1998]: Using Context
- Brill and Moore [2000]: String-to-String Edits
- Toutanova and Moore [2002]: Pronunciation Modeling
Kernighan, Church and Gale [1990]:
Using the Noisy Channel Model

• The problem:
  – Given a word in error, find the most likely word intended by the author

• Approach:
  – Find all words within edit distance of 1
  – Determine the probability of each possible edit from a corpus
  – Use these probabilities to order the list of candidates
Kernighan, Church and Gale [1990]: An Example: Candidate Corrections

<table>
<thead>
<tr>
<th>Typo</th>
<th>Correction</th>
<th>Transformation</th>
</tr>
</thead>
<tbody>
<tr>
<td>across</td>
<td>actress</td>
<td>@ t 2</td>
</tr>
<tr>
<td>across</td>
<td>cress</td>
<td>a # 0</td>
</tr>
<tr>
<td>across</td>
<td>caress</td>
<td>ac ca 0</td>
</tr>
<tr>
<td>across</td>
<td>access</td>
<td>r c 2</td>
</tr>
<tr>
<td>across</td>
<td>across</td>
<td>e o 3</td>
</tr>
<tr>
<td>across</td>
<td>acres</td>
<td>s # 4</td>
</tr>
<tr>
<td>across</td>
<td>acres</td>
<td>s # 5</td>
</tr>
</tbody>
</table>
Kernighan, Church and Gale [1990]: Using the Noisy Channel Model

- We want to find the most likely correction \( c \) given a misspelling \( t \)
- By Bayes Rule, this means finding the \( c \) that maximizes

\[
Pr(c) \cdot Pr(t|c)
\]

Prior model of word probabilities | The channel (or error) model
Kernighan, Church and Gale [1990]:
Prior Probabilities

- $\Pr(c)$ is estimated by:
  \[
  \frac{freq(c) + 0.5}{N}
  \]
- where $freq(c)$ is the number of times that the word $c$ appears in the 1988 AP corpus ($N = 44$ million words)
Kernighan, Church and Gale [1990]: Conditional Probabilities

\[ Pr(t|c) = \begin{cases} 
\frac{\text{del}[c_{p-1}, c_p]}{\text{chars}[c_{p-1}, c_p]}, & \text{if deletion} \\
\frac{\text{add}[c_{p-1}, t_p]}{\text{chars}[c_{p-1}]}, & \text{if insertion} \\
\frac{\text{sub}[t_p, c_p]}{\text{chars}[c_p]}, & \text{if substitution} \\
\frac{\text{rev}[c_p, c_{p+1}]}{\text{chars}[c_p, c_{p+1}]], & \text{if reversal} 
\end{cases} \]

- \textit{del}, \textit{add}, \textit{sub} and \textit{rev} are derived from \underline{confusion matrices}
- \textit{chars} are occurrence counts derived from the corpus
Kernighan, Church and Gale [1990]: Confusion Matrices
Kernighan, Church and Gale [1990]:
The Example: Scoring the Candidates

| Correction | Score | Raw | freq (c) | Pr(t | c) |
|------------|-------|-----|----------|--------|
| actress    | 37%   | .157| 1343     | 55/470,000 |
| cress      | 0%    | .000| 0        | 46/32,000,000 |
| caress     | 0%    | .000| 4        | 0.95/580,000 |
| access     | 0%    | .000| 2280     | 0.98/4,700,000 |
| across     | 18%   | .077| 8436     | 93/10,000,000 |
| acres      | 21%   | .092| 2879     | 417/13,000,000 |
| acres      | 23%   | .098| 2879     | 205/6,000,000 |
Kernighan, Church and Gale [1990]: The Example in Context

... was called a "stellar and versatile actress whose combination of sass and glamour has defined her ...."
Kernighan, Church and Gale [1990]: Performance

- Test sample of 329 misspelled words with two candidate corrections
- Program agrees with majority of judges in 87% of cases
Approaches to Spelling Correction

- Yannakoudakis and Fawthrop [1983]: Error Patterns
- Kernighan, Church and Gale [1990]: The Noisy Channel Model
- Agirre et al [1998]: Using Context
- Brill and Moore [2000]: String-to-String Edits
- Toutanova and Moore [2002]: Pronunciation Modeling
Agirre et al [1998]: Using Context

• The Goal:
  – **Given a non-word error, use the context to determine the most likely correction (the ‘single proposal’)***
Agirre et al [1998]: Sources of Knowledge

- **Statistical:**
  - Brown Corpus (BF) and document (DF) word frequencies

- **Syntactic:**
  - Constraint Grammar (CG) used to rule out candidate corrections that are grammatically unacceptable

- **Semantic:**
  - Use distance in WordNet (CD) to choose the candidate noun correction that is closest to the words in the context
Agirre et al [1998]: Performance

- A large number of combinations tried on artificially generated error data
- Best performing combinations tested on real error data
- Main findings:
  - Combination of syntax and document frequencies works best
    - But effect of document frequency impacted by small documents
  - Brown Corpus frequencies and conceptual density not useful
Approaches to Spelling Correction

- Yannakoudakis and Fawthrop [1983]: Error Patterns
- Kernighan, Church and Gale [1990]: The Noisy Channel Model
- Agirre et al [1998]: Using Context
- Brill and Moore [2000]: String-to-String Edits
- Toutanova and Moore [2002]: Pronunciation Modeling
Brill and Moore [2000]: Improving the Noisy Channel Model

• The Approach:
  – Given a word assumed to be in error, use a noisy channel model based on string to string edits to determine candidate corrections
Brill and Moore [2000]: Approach

• Generalise the error model to permit generic string to string edits
  \( \Pr(\alpha \rightarrow \beta) \) \ is \ the \ probability \ that \ the \ user \ types \ \beta \ when \ they \ meant \ \alpha \)

• Edits are conditioned on position in the string:
  – \( \Pr(\alpha \rightarrow \beta | \text{PSN}) \) \ where \ \text{PSN} = \text{start, middle, or end of word} \)

• Observation:
  – \( P(e | a) \) \ does \ not \ vary \ by \ location
  – \( P(\text{ent} | \text{ant}) \) \ does
Brill and Moore [2000]: Example

- Spelling error:
  - physical $\rightarrow$ fisikle

- Conceptually, the user picks a word; partitions it into substrings; generates each partition, perhaps erroneously
  - ph+y+s+i+c+al $\rightarrow$ f+i+s+i+k+le

- Probability of generating the error is then:
  - $P(f \mid ph) \cdot P(i \mid y) \cdot P(s \mid s) \cdot P(i \mid i) \cdot P(k \mid c) \cdot P(le \mid al)$
Brill and Moore [2000]: Learning the Model

- String to string edits are derived from mismatches in aligned \(\langle\text{spelling error, correction}\rangle\) pairs:

  A C T U A L
  
  //   \   \   \   \   
  A K G S U A L

- Edits derived:
  
  c \rightarrow k, \ ac \rightarrow ak, \ c \rightarrow kg, \ ac \rightarrow akg, \ ct \rightarrow kgs
Brill and Moore [2000]:
Testing

- 10000 word corpus of spelling errors + corrections
- 200k word dictionary
- Language model assigns uniform probabilities to all words
Brill and Moore [2000]:

Spell Checking

• What’s a Spelling Error?
• Non-Word Error Detection
• Error Correction
• Real-Word Error Detection
Real Word Errors are a Real World Problem

• Peterson:
  – 10% of typing errors are undetected when using a 50k word dictionary
  – 15% are undetected when using a 350k word dictionary

• Two Main Approaches in the Literature:
  1. Try to determine from contextual evidence whether a word is a real-word error
  2. Given a potential real-word error, determine the most likely correction
Mays, Damaraue and Mercer [1991]: Using Trigrams to Detect Real-Word Errors

• The Goal:
  – Given a text, determine presence of real-word errors and propose candidate corrections

• Basic Idea:
  – If the trigram-derived probability of an observed sentence is lower than that of any sentence obtained by replacing one of the words with a spelling variation, then hypothesize that the original is an error and the variation is what the user intended.
Mays, Damereau and Mercer [1991]:
The Idea

• Example:
  – I saw the man it the park

• Syntax can be used:
  – to determine that an error is present
  – to determine whether candidate corrections result in grammatical strings

• But we don’t have 100% reliable parsers, so try something else: a trigram language model
The Key Insights

- A low-probability word sequence can be considered evidence for a real-word error
- High-probability sequences can be used to rank correction candidates
Mays, Damerau and Mercer [1991]: The Data

- Restricted to edit distance 1 errors, and one misspelled word per sentence
- Given a set of 100 randomly selected sentences:
  - For each sentence, generate all possible sentences where each word is subjected to edit distance 1 transformations
  \[\Rightarrow\text{8628 misspelled sentences}\]
Mays, Damereau and Mercer [1991]: The Noisy Channel Model

- We want to find the most likely correction $w$ given a misspelling $x$
- By Bayes Rule, this means finding the $w$ that maximizes

$$Pr(w). Pr(x|w)$$

The channel model

Prior model of word probabilities, approximated using the trigram model
Mays, Damerau and Mercer [1991]: The Noisy Channel Model

- The channel model:

\[
P(x|w) = \begin{cases} 
\alpha & \text{if } x = w \\
(1 - \alpha)/|SV(w)| & \text{if } x \in SV(w) \\
0 & \text{otherwise}
\end{cases}
\]

- \(SV(w)\) is the set of spelling variations of \(w\); all are considered equally likely

- The challenge: find the optimal value for \(\alpha\), the a priori belief that the observed input word is correct
Mays, Damerau and Mercer [1991]: Performance

<table>

- original = %age of original input sentences changed to some other sentence
- changed = %age of misspelled sentences changed to some other sentence
- correct = %age of changed misspelled sentences that were changed correctly
- composite = %age of misspelled sentences that were changed correctly
Mays, Damerau and Mercer [1991]: Observations

- As $\alpha$ increases the correctness of the changes increases
- As $\alpha$ increases the percentage of misspelled sentences changed to some other sentence decreases
- A reasonable value for $\alpha$ lies in the range 0.99–0.999

See Wilcox-O’Hearn, Hirst and Budanitsky [2008] for a rational reconstruction and proposals for improvements
The Goal:

- Determine real-word errors on the basis of their semantic incompatibility with the rest of the text

Basic idea:

- Words which are semantically unrelated to the context, but whose spelling variations are related to the context, are possible real-world spelling errors
Hirst and Budanitsky [2005]: Syntax Doesn’t Always Help

- It is my sincere hope that you will recover swiftly.
- The committee is now not prepared to grant your request.
Hirst and Budanitsky [2005]: The Underlying Observation

- Linguistic cohesion is maintained by **lexical chains**: words linked by lexical and semantic relationships
  - literal repetition
  - coreference
  - synonymy
  - hyponymy
A real-word spelling error is unlikely to be semantically related to the text.

Usually, the writer’s intended word will be semantically related to nearby words.

It is unlikely that an intended word that is semantically unrelated to all those nearby will have a spelling variation that is related.

So: detect tokens that fit into no lexical chain in the text and replace them with words for which they are plausible mistypings that do fit into a lexical chain.
Hirst and Budanitsky [2005]: Requirements

- A mechanism for generating candidate spelling variations
  - For example, all real words in edit distance 1
- A mechanism for determining whether two words are semantically related
  - For example, distance measures in WordNet
Hirst and Budanitsky [2005]: The Approach

- Ignore words not in the lexicon, closed class words, and elements of a list of non-topical words (e.g., know, find, world).

- For any remaining suspect:
  - Determine if it is semantically related to another word in the text.
  - If not, then look for positive evidence: is any spelling variation a better fit?
Hirst and Budanitsky [2005]: Performance

But: Wilcox-O’Hearn et al [2008] show that the Mays, Damerau, and Mercer model performs better.
Whitelaw et al [2009]: The Web as a Corpus for Spelling Correction

• Basic idea:
  – Use the web as a large noisy corpus to infer knowledge about misspellings and word usage
  – Avoid using any manually-annotated resources or explicit dictionaries

• Important feature: easily ported to other languages
Whitelaw et al [2009]:
Approach

- Infer information about misspellings from term usage observed on the Web, and use this to build an error model
- The most frequently observed terms are taken as a noisy list of potential candidate corrections
- Token n-grams are used to build a language model which is used to make context-appropriate corrections
Whitelaw et al [2009]:
Key Feature

- Given error and LM scores, confidence classifiers determine the thresholds for spelling error detection and auto-correction
- Classifiers are trained on clean news data injected with artificial misspellings
Whitelaw et al [2009]:
System Architecture

Diagram showing the flow of input text through a system architecture based on term list, error model, and language model to generate scored suggestions. These suggestions are then fed into classifiers, which use confidence to produce corrected text. Data sources include the Web and news data with artificial misspellings.
Whitelaw et al [2009]: Candidate Corrections

• The Term List:
  – The 10 million most frequently occurring tokens from a > 1 billion sample of web pages (so it’s noisy)

• The Error Model:
  – A substring model like Brill and Moore’s
  – Built using ⟨intended word, misspelling⟩ pairs inferred from the web

• The Language Model:
  – Derived from the web, of course
Whitelaw et al [2009]:
Performance

• Total error rate for best configuration reduces the error of the best aspell system from 4.83% to 2.62% on artificial data
• Total error rate reduces the error of the best aspell system from 4.58% to 3.80% on human English data
• Total error rate reduces the error of the best aspell system from 14.09% to 9.80% on human German data
A Road Map

Correcting Non-Word Errors

- Yannakoudakis and Fawthrop 1983: Error Rules
- van Berkel and De Smedt 1988: Triphone Analysis
- Kernighan, Church and Gale 1990: The Noisy Channel Model
- Brill and Moore 2000: Noisy-Channel with String Edits
- Toutanova and Moore 2002: Phonological Error Model

Correcting Real-Word Errors

- Golding 1995: Trigram Model
- Golding and Schabes 1996: Trigram + Bayes
- Mangu and Brill 1997: Transformation-Based Learning

All Words

- Mays, Damerau and Mercer 1991: Trigram Language Model
- Hirst and Budanitsky 2005: Using Semantics

Confusion Sets

- Whitelaw et al 2009: Using The Web
Conclusions

• Methods for generating candidate corrections for a word known to be in error are now very sophisticated
  – The noisy channel model is a good fit
  – Lots of scope for refinement in the language model and the error model
• Determining when a word has been misspelled as another word is an AI-hard problem …
• … but Google-scale language modelling does surprisingly well

The Need

Grammar Checker

You might have asked yourself before sending an important email to a business colleague or a new friend:

"Will this text read better if I perform a grammar check?"

You are not alone! People all around the world find themselves asking this question when trying to avoid grammar mistakes in their texts.

Grammar Checker – The Ultimate Solution for Your Grammar Errors
Proofread your text in a single click by using an online grammar checker.
An online grammar checker will save you the embarrassment of sending a text with grammar mistakes and will make your text look more professional and reliable.

What is a Grammatical Error?

• Something that breaks the rules of the language
• Who decides?
  – Dialects
  – Formality
  – Language change
• Some jurisdictions are stricter than others
  – L'Académie française and its 40 ‘immortals’
Agreement Errors: The Paradigm Grammatical Error

- John and Mary is coming today.
- The block are red.
- A blocks are red.
Taxonomies of Error: Douglas and Dale 1991

- Spelling Errors
- Syntactic Errors
  - Semantic Problems
  - Stylistic Problems
  - Rhetorical Problems
- Punctuation Problems

Co-occurrence Errors
- Number Disagreement
- Bad Subcategorisation
- Resumptive Pronoun
- Syntactic Parallelism

Dependency and Subordination Errors
- Bad Clause Conjunction
- Misleading PP Attachment
- Misleading Adverbial Attachment
- Missing Subordination Indicator
- Redundancy
Subject–Verb Number Disagreement

• But the males in this study experienced significant difficulties in this area and this problem suggest that some more attention be paid to the phenomenon.

• This method requires a user to think aloud while performing a task, while the researchers makes notes, and perhaps records the session on audio or video tape.

• The main reported problems was the Unix editor vi.
Subject–Verb Number Disagreement

→ The feature checklist was easy to administer and **easy for experienced users to complete** . . .
• Semi-structured interviews were conducted with experienced users to find what their most common tasks, the tasks a new user would need to begin, and what errors would be most likely in the early stages.
Semi-structured interviews were conducted with experienced users to find what their most common tasks were, what tasks a new user would need to begin, and what errors would be most likely in the early stages.
Bad Clause Conjunction

- It had approximately 13% of the pages of the commercial manual, it allowed 30% faster learning and more effective use of the email system overall, and significantly better performance on individual subtasks including recovery from error.
Bad Clause Conjunction

- It had approximately 13% of the pages of the commercial manual, it allowed 30% faster learning and more effective use of the email system overall, and significantly better performance on individual subtasks including recovery from error.

  → It had approximately 13% of the pages of the commercial manual, it allowed 30% faster learning and more effective use of the email system overall, and it gave significantly better performance on individual subtasks including recovery from error.
Bad Clause Conjunction

• The conditions under which our subjects worked tended to minimize such problems — since we asked them to persevere, and in the end they would be able to get human help.
Bad Clause Conjunction

- The conditions under which our subjects worked tended to minimize such problems — since we asked them to persevere, and in the end they would be able to get human help.

The conditions under which our subjects worked tended to minimize such problems, since we asked them to persevere, and in the end they would be able to get human help.
Bad Clause Conjunction

• The more active but ineffectual behaviour of the males may mean that they feel they must be capable of mastering the system, of overcoming their errors and are less worried or affected by the possibility of making errors.
The more active but ineffectual behaviour of the males may mean that they feel they must be capable of mastering the system and of overcoming their errors, and are less worried or affected by the possibility of making errors.
Bad Clause Conjunction

- Novice users should, however, be able to voice thoughts and desires on any topic, throughout the process if the manual is to be properly user-centred.
Novice users should, however, be able to voice thoughts and desires on any topic, throughout the process if the manual is to be properly user-centred.

However, if the manual is to be properly user-centred, novice users should be able to voice thoughts and desires on any topic throughout the process.
Syntactic Redundancy

• So although this seems to be is a winning feature in learning, it may not …

• … this problem suggests that some more attention be paid to the phenomenon

• … thus so this argues for the complementary use of …
Syntactic Redundancy

• So although this seems to be is a winning feature in learning, it may not …

• … this problem suggests that some more attention be paid to the phenomenon

• … thus so this argues for the complementary use of …
What Causes Grammar Errors?

- Competence-based errors (Errors of Intention):
  - Unfamiliarity with the language
- Performance-based errors (Errors of Execution):
  - Repeated words
  - Editing errors

The Unix Writer’s Workbench

- A breakthrough in the early 1980s
  - We believe that the Writer's Workbench programs provide a more general text analysis system than JOURNALISM or CRES, and unlike EPISTLE they are already in wide use. At Bell Laboratories there are over 1000 users on over 50 machines. [1982:106]
- Widely-used in educational contexts
- Underlying technology formed the basis for the first PC grammar checkers: Grammatik, RightWriter, StyleWriter
The Unix Writer’s Workbench: Proofreading with PROOFR

- Checks for existence of non-word spelling errors; user-specified automatic correction can be carried out
- Checks for unbalanced punctuation and other simple punctuation mistakes
- Checks for double words
- Checks for misused words, wordy phrases, sexist terms, …
- Checks for split infinitives using a simple PoS tagger
The Unix Writer’s Workbench: Stylistic Analysis with STYLE

• Based on PoS tagging, provides 71 numbers describing stylistic features of the text
  – Readability indices
  – Average sentence and word length
  – Distribution of sentence lengths
  – Percentage of verbs in passive voice
  – Percentage of nouns that are nominalisations
  – …
The Unix Writer’s Workbench: Stylistic Analysis with STYLE

readability grades:
(Kincaid) 11.3 (auto) 12.6 (Coleman-Liau) 13.1 (Flesch) 13.2 (48.8)

expletives 1% (2)
The Unix Writer’s Workbench: Other Components

• PROSE: compares the stylistic parameters of a given text against a domain-specific standard
• ABST: determines the conceptual abstractness of a text via a list of 314 abstract words
• ORG: prints only first and last sentences of paragraphs
Atwell [1987]:

**CLAWS**

- Originally built to assign PoS tags to the London-Oslo-Bergen corpus
- Developed in part because of the computational cost of more complex systems:
  - ‘[Heidorn et al 82] reported that the EPISTLE system required a 4Mb virtual machine (although a more efficient implementation under development should require less memory).’ [1987:38]
Atwell [1987]: Constituent-Likelihood Error Detection

- For PoS tagging, uses a table of PoS bigram frequencies to determine most likely sequences
- Detects grammatical errors by flagging unlikely PoS transitions
- Doesn’t need separate data for training error likelihoods
Outline

• What is a Grammatical Error?
• Grammar Checking without Syntax
  • IBM’s EPISTLE
• Grammar Checking Techniques
• Related Areas
• Commercial Packages
IBM’s EPISTLE: History

- Initial work in the early 1980s led to several innovative techniques
- Based on Heidorn’s Augmented Phrase Structure Grammar [1975]
- Renamed CRITIQUE somewhere in the mid to late 1980s
- Released on IBM mainframes late 1980s
- Key team members went on to build Microsoft Word’s grammar checker from 1992 onwards
- Grammar checking released as part of MS Word 97
IBM’s CRITIQUE: Grammar vs Style

• Grammatical critiques:
  – Strict rules as to whether a sentence is grammatical or not
  – Correction is typically clear

• Stylistic weaknesses are less black and white:
  – too great a distance between subject and verb
  – too much embedding
  – unbalanced subject/predicate size
  – excessive negation or quantification
  – …
IBM’s CRITIQUE: Grammar Errors

- **Number Disagreement:**
  - he go, many book, it clarifies and enforce

- **Wrong Pronoun Case:**
  - between you and I, it is me

- **Wrong Verb Form:**
  - had expect, seems to been

- **Punctuation:**
  - run-on sentences, questions with a final period instead of a question mark

- **Confusions:**
  - who’s vs whose, it’s vs its, your vs you’re, form vs from
IBM’s CRITIQUE: Stylistic Weaknesses #1

• Excessive length
  – Sentences or lists that are too long
  – Sequences with too many prepositional phrases

• Excessive complexity
  – Noun phrases with too many premodifiers
  – Clauses with a series of *ands*
  – Verb phrases with too many auxiliary verbs
  – Clauses with too much negation

• Lack of parallelism
  – Example: you should drink coffee rather than drinking tea
IBM’s CRITIQUE: Stylistic Weaknesses #2

• Excessive formality
  – phrases that are bureaucratic, pompous or too formal
• Excessive informality
  – constructions acceptable in spoken English but too informal when written
• Redundancy
  – phrases that can be shortened without loss in meaning
• Missing punctuation
• Nonpreferred constructions
  – Split infinitives [eg to completely remove], colloquial usage [eg ain’t working]
The MS Word Grammar Checker: Processing Steps

1. Tokenisation and Lexical Lookup
2. Syntactic Sketch
3. Syntactic Portrait
4. Production of Logical Forms
The MS Word Grammar Checker: An Example

• Consider the following sentence:
  – After running a mile he seemed tired.
The MS Word Grammar Checker: Lexical PoS Records

- Also includes detection of multiword elements and named entity mentions
- Lexicon based on LDOCE and AHD + supplementary information added both manually and automatically
- Over 100k words
- There are two other records produced for ‘after’ here for the Adj and Adv uses

```
{Segtype  PREP
 Nodetype  PREP
 Nodename  PREP1

Comma with Adverbials:

- After running a mile consider: After running a mile,

After running a mile he seemed tired.

Comma Use

To make your sentence easier to read or to signal a pause, consider using a comma to set off words or phrases (especially introductory words or phrases).

- Instead of: Unfortunately it rained the day of the picnic.
  Consider: Unfortunately, it rained the day of the picnic.

- Instead of: Once he got home he began to calm down.
  Consider: Once he got home, he began to calm down.
The MS Word Grammar Checker: Controlling the Checker’s Behaviour
EPISTLE/CRITIQUE/MS Word: Key Ideas

- A metric for ranking alternative parses [Heidorn 1982]
- Relaxation for parsing errorred sentences [Heidorn et al 1982]
- A heuristic fitted parsing technique for sentences outside the grammar’s coverage [Jensen et al 1983]
Outline

• What is a Grammatical Error?
• Grammar Checking without Syntax
• IBM’s EPISTLE
  • Grammar Checking Techniques
• Related Areas
• Commercial Packages
Constraint Relaxation:  
The Basic Idea

• When a sentence cannot be parsed, relax the grammar rules in some way so that it can be parsed
• The particular constraints that are relaxed indicate what the nature of the grammatical error is
• First explored in the context of robust parsing by Weischedel and Black [1980]
Constraint Relaxation:
Handling Constraint Violation Errors

• Subject-verb number agreement
  * John and Mary runs

• Premodifier-noun number agreement
  * This dogs runs

• Subject-complement number agreement
  * There is five dogs here

• Wrong pronoun case
  * He and me ran to the door

• Wrong indefinite article
  * A apple and a rotten old pear.
Constraint Relaxation: Handling Constraint Violation Errors

• A number agreement constraint in PATR-II:

\[
\begin{align*}
X_0 & \rightarrow X_1 X_2 \\
\langle X_0 \text{ cat} \rangle & = \text{VP} \\
\langle X_1 \text{ cat} \rangle & = \text{NP} \\
\langle X_2 \text{ cat} \rangle & = \text{VP} \\
\langle X_0 \text{ subject} \rangle & = X_1 \\
\langle X_1 \text{ num} \rangle & = \langle X_2 \text{ num} \rangle
\end{align*}
\]
Constraint Relaxation [Douglas and Dale 1992]:
Relaxation Packages

\[ X_0 \rightarrow X_1 X_2 \]

1. \( \langle X_0 \text{ cat} \rangle \) = NP
2. \( \langle X_1 \text{ cat} \rangle \) = Det
3. \( \langle X_2 \text{ cat} \rangle \) = N
4. \( \langle X_1 \text{ agr precedes} \rangle \) = \( \langle X_2 \text{ agr begins} \rangle \)
5. \( \langle X_1 \text{ agr num} \rangle \) = \( \langle X_2 \text{ agr num} \rangle \)
6. \( \langle X_0 \text{ agr num} \rangle \) = \( \langle X_2 \text{ agr num} \rangle \)

Relaxation level 0:
necessary constraints = \{1,2,3,4,5,6\}
optional constraints = \{

Relaxation level 1:
necessary constraints: \{1,2,3\}
relaxation packages:
(a) \{5, 6\}: Prenoun noun number disagreement
(b) \{4\}: \text{a/an} error
Constraint Relaxation

• Advantages:
  – provides a precise and systematic way of specifying the relationship between errorful and ‘correct’ forms, making it easier to generate suggestions for corrections

• Disadvantages:
  – Requires significant amounts of hand-crafted linguistic knowledge
Mal-Rules

- Also known as error anticipation
- Mal-rules explicitly describe specific expected error forms
A Mal-Rule for Handling Omissions
[Schneider and McCoy 1998]

• Example:
The boy happy

• Conventional rule:
  VP → V AdjP

• Malrule:
  VP[error +] → AdjP
Mal-Rules

• Advantage:
  – Specifically targets known problems
  – Allows easy identification of the nature of the error

• Disadvantages:
  – Requires error types to be catalogued in advance
  – Infeasible to anticipate every possible error

• Arguably mal-rules are just a notational variant of constraint relaxation approaches
Other Approaches

- Fitted parsing [Jensen et al 1983]
- Mixed bottom-up and top-down parsing [Mellish 1989]
- Minimum edit distance parsing [Lee et al 1995]
Outline

• What is a Grammatical Error?
• Grammar Checking without Syntax
• IBM’s EPISTLE
• Grammar Checking Techniques
  • Related Areas
• Commercial Packages
Robust Parsing

• The Goal:
  – Analyse extragrammatical input in order to extract some useful meaning
• No need to characterise and repair the error
• Processing of spoken language is a special case
Controlled Languages

• The Goal:
  – Ensure that a text conforms to a specific set of rules and conventions

• Examples:
  – ASD Simplified Technical English
  – Caterpillar Technical English
  – EasyEnglish
  – Attempto Controlled English

• See http://www.geocities.ws/controlledlanguage/

John and Mary is coming today.

The main reason for this delay is that the server was experiencing significant difficulties in this area and this problem suggest that some more attention be paid to it. This method, while performing a task, while the researchers makes notes, and perhaps even tape.

In Unix editor vi.

However, has tended to use existing commercial manuals as a basis --- and the editors of their original size, and to alter their contents to approach more closely to the problem.

Their feedback pointed to problem areas and causes for misinterpretation, and suggestions of improvements offered by them.

In this way, it is anticipated that the issue of native users not really knowing what it is they need to know is dealt with. All mailing systems have capabilities of composing, sending and receiving messages. The feature checklist was easy to administer and complete by experienced users.

Semi-structured interviews were conducted with experienced users to find what their most common tasks, the tasks a new user would need to begin, and what errors would be most likely in the early stages.

It had approximately 13% of the pages of the commercial manual, it allowed 30% faster learning and more effective use of the email system overall, and significantly better performance on individual subtasks including recovery from error.

The conditions under which our subjects worked tended to minimize such problems – since we asked them to persevere, and in the end they would be able to get human help.
John and Mary is coming today.

A blocks are red.

But the males in this study experienced significant difficulties in this area and this problem suggest that some more attention be paid to the phenomenon.

This method requires a user to think aloud a task, while the researchers makes notes, and perhaps records the session on audio or video tape. The main reported problems was the Unix.

Both Carroll's work and our own, however, lead to a common conclusion of the existing commercial manuals as a basis --- and the question then is how to prune to a fraction of the problems that users actually confront, and to alter their contents to approach more closely to the problems that users actually confront.

Their feedback pointed to problem areas and issues of interpretation, and suggestions of improvements offered by them.

In this way, it is anticipated that the issue of native users not really knowing what it is they need to know is dealt with.

All mailing systems have capabilities of composing, sending and receiving messages.

The feature checklist was easy to administer and complete by experienced users.

Title
Some Sample Grammar Problems

to the problems that users actually confront when trying to learn a new system. Their feedback pointed to problem areas and causes for misinterpretation, and suggestions of improvements offered by them.

In this way, it is anticipated that the issue of native users not really knowing what it is they need to know is dealt with. All mailing systems have capabilities of composing, sending and receiving messages. The feature checklist was easy to administer and complete by experienced users. Semi-structured interviews were conducted with experienced users to find what their most common tasks, the tasks a new user would need to begin, and what errors would be most likely in the early stages. It had approximately 13% of the pages of the commercial manual, it allowed 30% faster learning and more effective use of the email system overall, and significantly better performance on individual subtasks away from error.

The conditions under which our subjects worked tended to minimize such problems – since persevere, and in the end they would be able to get human help. The more active but ineffectual behaviour of the males may mean that they feel they must persevere, and in the end they would be able to get human help. Novice users should, however, be able to voice thoughts and desires on any topic, through the manual is to be properly user-centred.
Conclusions

• Grammar checking is hard even for humans
• Automated grammar checking is a very unsolved problem
• Grammar checking is not necessarily distinct from spelling checking and style checking
• Many of the problems in real texts are more complex than straightforward textbook grammar errors, and often co-occur with other errors
• There’s lots to be done!
Overview

• Introduction: The Need
• Spell Checking
• Grammar Checking
• Helping Non-Native Speakers
• Beyond Spelling and Grammar Checking
• Conclusions
Outline

• Background
• Article Errors
• Preposition Errors
• Other ESL Problems
• Conclusions
Terminology

- **ESL** = English as a Second Language
  - Refers to non-native speakers living and speaking in a predominantly English-speaking environment
- **EFL** = English as a Foreign Language
  - Refers to non-native speakers studying and learning English in a non-English speaking country
- We’ll generally use the term ESL to refer to both
- Apologies that this is mostly about ESL — there’s less work in other languages ...
The Problem

- Lots of people want to speak English: it is the most commonly studied second language
- Over 1 billion people speak English as a second or a foreign language
- Existing grammar checking tools are not, so far, tailored to the needs of ESL learners
ESL Errors Are Different: Bolt [1992]

• Bolt tested seven grammar-checking programs of the time against 35 sentences containing ESL errors

• Looked at from the perspective of a learner of English at a fairly low level of competence

• Conclusions:
  – ‘all of these programs fail in terms of the criteria that have been used.’
  – Expectations are encouraged that cannot be fulfilled
  – Silence on the part of a program suggests everything is ok

</table>
Common ESL Errors

• The most difficult aspects of English for ESL learners are:
  – Definite and indefinite articles
  – Prepositions
• Together these account for 20–50% of grammar and usage errors
• [But: spelling errors are much more common, and incorrect word choice is as problematic as article and preposition errors.]
What Causes the Problem?

- Articles:
  - Not present in all L1s
  - Correct article choice is very subtle and depends on a complex discourse and real world knowledge factors

- Prepositions:
  - Behaviour appears very idiosyncratic and unpredictable

Proportion of sentences with one or more preposition errors
A Note on Data

• The field has been hamstrung by the privately held nature of many learner corpora

• Two welcome changes:
  – The NUS Corpus of Learner English
  – The Cambridge Learner Corpus FCE Dataset

• Also the much smaller HOO dataset
NUCLE: The NUS Corpus of Learner English

• 1400 essays written by University students at the National University of Singapore
• Over 1M words annotated with error tags and corrections
• See http://nlp.comp.nus.edu.sg/corpora
Standoff annotation:

<MISTAKE start_par="4" start_off="194" end_par="4" end_off="195">
   <TYPE>ArtOrDet</TYPE>
   <CORRECTION>an</CORRECTION>
</MISTAKE>
The CLC FCE Dataset

• A set of 1,244 exam scripts written by candidates sitting the Cambridge ESOL First Certificate in English (FCE) examination in 2000 and 2001
• Annotated with errors and corrections
• A subset of the much larger 30M-word Cambridge Learner Corpus
• See http://ilexir.co.uk/applications/clc-fce-dataset/
The CLC FCE Dataset

Inline annotation:

- Because <NS type="UQ">all</i></NS> students in <NS type="MD">the</c></NS> English class are from all over the world …
The HOO Dataset

- HOO — Helping Our Own — aims to marshal NLP technology to help non-native speakers write ACL papers
- Very small corpus (~36K words) annotated with errors and corrections
- Evaluation software also freely available
- See http://www.clt.mq.edu.au/research/projects/hoo/
Stand-off and inline annotation both available:

• In our experiments, pseudo-words are fed into `<edit type="MD"><empty/><corrections><correction>the</correction></corrections></edit> PB-SMT pipeline.`

• `<edit index="1005-0016" type="MD" start="871" end="871" >
<original><empty/></original>
<corrections>
  <correction>the </correction>
</corrections>
</edit>`
Outline

• Background
• Article Errors
• Preposition Errors
• Other ESL Problems
• Conclusions
Article Errors

- The Problem
- Early Rule-based Approaches
- Knight and Chandler [1994]
- Han et al [2006]
- De Felice and Pulman [2008]
Why is Article Choice Hard?

- Basic problem for speakers of languages that do not use articles:
  - choose between a/an, the, and the null determiner
- The bottom line: it comes down to context
  - I was eating a cake.
  - I was eating the cake.
  - I was eating cake.
Features Impacting Article Choice: Countability

- Count nouns take determiners:
  - I read the paper yesterday.
- Mass nouns don’t take determiners:
  - We generally write on paper.
- But the universal grinder and the universal packager [Pelletier 1975] are always available:
  - There was dog all over the road.
  - Could we have just one rice please?
Features Impacting Article Choice: Countability

- Semi-idiomatic forms:
  - I looked him in the eye.
  - *I looked him in an eye.
Features Impacting Article Choice: Syntactic Context

✓ I have knowledge.
✗ I have a knowledge.
✓ I have knowledge of this.
✗ I have a knowledge of this.
✓ I have a knowledge of English.
Features Impacting Article Choice: Discourse Factors

- Stereotypically, entities are introduced into a discourse using an indefinite determiner and subsequently referred to using a definite determiner
  - I saw a man at the bus stop. ... The man was crying.
- But not always:
  - A bus turned the corner. The driver was crying.
  - I went to the beach yesterday.
Features Impacting Article Choice: World Knowledge

- He bought a Honda.
- He bought Honda.
Article Errors

- The Problem

- Early Rule-based Approaches
  - Knight and Chandler [1994]
  - Han et al [2006]
  - De Felice and Pulman [2008]
Early Work:  
Article Insertion in Machine Translation

• The Problem:
  – Machine translation of languages like Japanese or Russian into English is difficult because the source language doesn’t contain articles
Murata and Nagao [1993]:
Hand-Crafted Rules

- When a noun is modified by a referential pronoun (KONO(this), SONO(its), ...) then \{indefinite(0, 0), definite(1, 2), generic(0, 0)\}
- When a noun is accompanied by a particle (WA), and the predicate has past tense, then \{indefinite(1, 0), definite(1, 3), generic(1, 1)\}
- When a noun is accompanied by a particle (WA), and the predicate has present tense, then \{indefinite(1, 0), definite(1, 2), generic(1, 3)\}
- When a noun is accompanied by a particle HE(to), MADE(up to) or KARA(from), then \{indefinite(1, 0), definite(1, 2), generic(1, 0)\}
- ... 84 heuristics in total
Article Errors

• The Problem
• Early Rule-based Approaches
  • Knight and Chandler [1994]
  • Han et al [2006]
  • De Felice and Pulman [2008]
Knight and Chandler [1994]: A Data-Driven Method for Post-Editing

• General aim:
  – To build a post-editing tool that can fix errors made in a machine translation system

• Specific task:
  – Article insertion:  a, an or the
Stelco Inc. said it plans to shut down three Toronto-area plants, moving their fastener operations to a leased facility in Brantford, Ontario.

Company said fastener business “has been under severe cost pressure for some time.” Fasteners, nuts and bolts are sold to North American auto market.

Company spokesman declined to estimate impact of closures on earnings. He said new facility will employ 500 of existing 600 employees. Steelmaker employs about 16,000 people.
Knight and Chandler [1994]: The General Idea

The steps:
- Take newspaper-quality English text
- Remove articles
- Re-insert automatically
- Compare results with the original text

Assumptions:
- NPs are marked as singular or plural
- Locations of articles already marked so it’s a binary choice between *the* and *a/an.*
Knight and Chandler [1994]: Baseline

- In 40Mb of Wall Street Journal text:
  \[ a = 28.2\% \]
  \[ an = 4.6\% \]
  \[ the = 67.2\% \]
- So 67% is a good lower-bound
- Upper-bound:
  - Human subjects performed with accuracy of 94%-96%
Knight and Chandler [1994]: Baselines

<table>
<thead>
<tr>
<th></th>
<th>Human</th>
<th>Machine</th>
</tr>
</thead>
<tbody>
<tr>
<td>Random</td>
<td>50%</td>
<td>50%</td>
</tr>
<tr>
<td>Always guess <em>the</em></td>
<td>67%</td>
<td>67%</td>
</tr>
<tr>
<td>Given head noun + premodifiers (the ‘core NP’)</td>
<td>79-80%</td>
<td></td>
</tr>
<tr>
<td>Given core NP + 2 words either side</td>
<td>83-88%</td>
<td>?</td>
</tr>
<tr>
<td>Given full context</td>
<td>94-96%</td>
<td></td>
</tr>
</tbody>
</table>
Knight and Chandler [1994]:

**Approach**

- Characterize NPs via sets of features then build a decision tree to classify
- Lexical features:
  - ‘word before the article is *triple*’
- Abstract features:
  - ‘word after the head noun is a past tense verb’
- 400k training examples and 30k features; features with less than 4 instances discarded
Knight and Chandler [1994]: Performance

• On 1600 trees for the 1600 most frequent head nouns (covering 77% of test instances):
  – 81% accuracy
• Guess *the* for the remaining 23% of test instances
  – 78% accuracy overall
Article Errors

- The Problem
- Early Rule-based Approaches
  - Knight and Chandler [1994]
  - Han et al [2006]
  - De Felice and Pulman [2008]
Han et al [2006]:
A MaxEnt Approach to Article Selection

• Basic Approach:
  – A maximum entropy classifier for selecting amongst *a/an*, *the* or the null determiner
  – Uses local context features such as words and PoS tags
Han et al [2006]:
Contrasts with Earlier Work

• More varied training corpus: a range of genres instead of just one source:
  – 721 text files, 31.5M words
  – 10th thru 12th grade reading level
• Much larger training corpus: 6 million NPs (15x larger than Knight and Chandler’s)
  – Automatically PoS tagged + NP-chunked
• The use of a maximum entropy classifier
Han et al [2006]:
Training Results

• 6M NPs in training set
• 390k features
• Baseline = 71.84% (frequency of null determiner)
• Four-fold cross validation
  – performance range 87.59% to 88.29%
  – Average 87.99%
## Han et al [2006]: Effectiveness of Individual Features

<table>
<thead>
<tr>
<th>Feature</th>
<th>% Correct</th>
</tr>
</thead>
<tbody>
<tr>
<td>Word/PoS of all words in NP</td>
<td>80.41</td>

Han et al [2006]: Applying the Model to TOEFL Essays

- Model retrained only on NPs with a common head noun
  - Baseline = frequency of null determiner = 54.40%
  - Training set kept at 6M instances by adding more data
  - Average accuracy = 83.00%

- Model applied to 668 TOEFL essays w 29759 NPs
  - Subset of NPs classified by two annotators
  - Agreement on 98% of cases with kappa = 0.86
  - One article error every 8 NPs
Above all, I think it is good for students to share room with others.

- Human: missing a or an
- Classifier: 0.841 a/an, 0.143 the, 0.014 zero

Those excellent hitters began practicing the baseball when they were children, and dedicated a lot of time to become highly qualified.

- Human: superfluous determiner
- Classifier: 0.103 a/an, 0.016 the, 0.879 zero
Han et al [2006]: Results on TOEFL Essays

- 79% of errors in test set correctly detected
- Many false positives, so precision only 44%
- Decisions often borderline:
  - The books are assigned by professors.
  - Marked by annotators as correct, model predicts *the* (0.51) and null (0.49)
Han et al [2006]: Sources of Error

• Model performs poorly on decision between *a* and *the*
  – Probably due to the need for discourse information
• So, new feature: has the head noun appeared before, and if so, with what article?
  – No significant effect on performance
• Error analysis suggests this is due to more complex discourse behaviour:
  – A student will not learn if she hates the teacher.
  – … the possibilities that a scholarship would afford …
Article Errors

• The Problem
• Early Rule-based Approaches
• Knight and Chandler [1994]
• Han et al [2006]
• De Felice and Pulman [2008]
De Felice and Pulman [2008]: Richer Syntactic and Semantic Features

- Basic Approach:
  - As in Han et al [2006], a maximum entropy classifier for selecting amongst *a/an, the* or the null determiner
  - Use a richer set of syntactic and semantic features
De Felice and Pulman [2008]: Main Features

<table>
<thead>
<tr>
<th>Feature</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Head Noun</td>
<td>‘apple’</td>
</tr>
<tr>
<td>Number</td>
<td>Singular</td>
</tr>
<tr>
<td>Noun Type</td>
<td>Count</td>
</tr>
<tr>
<td>Named Entity?</td>
<td>No</td>
</tr>
<tr>
<td>WordNet Category</td>
<td>Food, Plant</td>
</tr>
<tr>
<td>Prepositional Modification?</td>
<td>Yes, ‘on’</td>
</tr>
<tr>
<td>Object of Preposition?</td>
<td>No</td>
</tr>
<tr>
<td>Adjectival Modification?</td>
<td>Yes, ‘juicy’</td>
</tr>
<tr>
<td>Adjectival Grade</td>
<td>Superlative</td>
</tr>
<tr>
<td>POS±3</td>
<td>VV, DT, JJS, IN, DT, NN</td>
</tr>
</tbody>
</table>

Example: Pick the juiciest apple on the tree.
De Felice and Pulman [2008]: Additional Features

- Whether the noun is modified by a predeterminer, possessive, numeral and/or a relative clause
- Whether it is part of a ‘there is …’ phrase
De Felice and Pulman [2008]: Performance

- Trained on British National Corpus
  - 4,043,925 instances
- Test set of 305,264 BNC instances
- Baseline = 59.83% (choose null)
- Accuracy = 92.15%
De Felice and Pulman [2008]: Comparative Performance on L1 Data

<table>
<thead>
<tr>
<th>Author</th>
<th>Accuracy</th>
</tr>
</thead>
<tbody>
<tr>
<td>Baseline</td>
<td>59.83%</td>
</tr>
<tr>
<td>Han et al 2006</td>
<td>83.00%</td>
</tr>
<tr>
<td>Gamon et al 2008</td>
<td>86.07%</td>
</tr>
<tr>
<td>Turner and Charniak 2007</td>
<td>86.74%</td>
</tr>
<tr>
<td>De Felice and Pulman 2008</td>
<td>92.15%</td>
</tr>
</tbody>
</table>
De Felice and Pulman [2008]: Results on Individual Determiners

<table>
<thead>
<tr>
<th></th>
<th>% of Training Data</th>
<th>Precision</th>
<th>Recall</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>9.61% (388,476)</td>
<td>70.52%</td>
<td>53.50%</td>
</tr>
<tr>
<td>the</td>
<td>29.19% (1,180,435)</td>
<td>85.17%</td>
<td>91.51%</td>
</tr>
<tr>
<td>null</td>
<td>61.20% (2,475,014)</td>
<td>98.63%</td>
<td>98.79%</td>
</tr>
</tbody>
</table>

- The indefinite determiner is less frequent and harder to learn
De Felice and Pulman [2008]:
Testing on L2 Text

- 3200 instances extracted from the CLC
  - 2000 correct
  - 1200 incorrect
- Accuracy on correct instances: 92.2%
- Accuracy on incorrect instances: < 10%
- Most frequent incorrect usage is a missing determiner
  - Model behaviour influenced by skew in training data
- Also problems in extracting NLP features from L2 data

</tbody>
</table>

Proportion of sentences in the CLC with one or more preposition errors
Prepositions Have Many Roles in English

• They appear in adjuncts:
  – *In* total, I spent $64 million dollars.

• They mark the arguments of verbs:
  – I’ll give ten cents *to* the next guy.

• They figure in phrasal verbs:
  – I *ran away* when I was ten.

• They play a part in idioms:
  – She *talked down* to him.
Negative Transfer

• Many prepositions have a most typical or frequent translation
  – Eg: *of* in English to *de* in French

• But for many prepositions there are multiple translational possibilities
  – ESL speakers can easily choose the wrong one
  – Eg: driving *in* a high speed
Prepositions in English

- English has over 100 prepositions, including some multiword prepositions and a small number of postpositions
- The 10 most frequent account for 82% of the errors in the CLC

Upcoming Shared Task

- HOO 2012 at the Building Educational Applications Workshop at NAACL 2012
- Preposition and Determiner Error Correction
- See www.correcttext.org/hoo2012
- Schedule:
  - Friday 27th January: Registration opens
  - Friday 6th April: Test data for evaluation released
  - Friday 13th April: Deadline for submissions for evaluation.
  - Friday May 4th: Team reports deadline for proceedings
Outline

• Background
• Article Errors
• Preposition Errors
  • Other ESL Problems
• Conclusions
Collocations

- Conventional combinations that are preferred over other equally syntactically and semantically valid combinations
  - Adj + Noun: stiff breeze vs rigid breeze
  - Verb + Noun: hold an election vs make an election
  - Noun + Noun: movie theatre vs film theatre
  - Adverb + Verb: thoroughly amuse vs completely amuse
Collocations

• Computational approaches generally make use of distributional differences for detecting and correcting errors

• Same general approach as in articles and prepositions:
  – Choose preferred form from a set of alternatives
  – But: the confusion set is potentially much larger

• Solution:
  – Constrain the space by selecting alternatives with a similar meaning

• See work on automatic thesaurus construction [eg Lin 1998]
Verb Form Errors

The Nature of Revision

Faigley and Witte 1981

Figure 1. A Taxonomy of Revision Changes

Faigley and Witte 1981
Meaning-Preserving Changes: Additions

Additions make explicit what can be inferred:

• you pay two dollars → you pay a two dollar entrance fee
Deletions remove explicit elements and force the reader to infer:

• several rustic looking restaurants → several rustic restaurants
Meaning-Preserving Changes: Substitutions

Substitutions replace words or phrases with other synonymous content:

• out-of-the-way spots → out-of-the-way places
Permutations rearrange material, possibly with substitutions:

- springtime means to most people
  → springtime, to most people, means
Distributions move material from one segment into multiple segments:

• I figured after walking so far the least it could do would be to provide a relaxing dinner since I was hungry.

→

I figured the least it owed me was a good meal. All that walking made me hungry.
Meaning-Preserving Changes: Consolidations

Consolidations move material from multiple units into a single unit:

• And there you find Hamilton's Pool. It has cool green water surrounded by 50-foot cliffs and lush vegetation.

→

And there you find Hamilton's Pool: cool green water surrounded by 50-foot cliffs and lush vegetation.
Are These Revisions Automatable?

- The relevant ideas are already a focus in various sub-areas of NLP:
  - Paraphrase, Text Simplification and Lexical Simplification
  - Recognizing Textual Entailment
  - Surface Realisation
  - Sentence Aggregation

The Nature of Revision

Figure 1. A Taxonomy of Revision Changes

Faigley and Witte 1981
Meaning Changes

• **Macrostructure changes**
  – Would change a summary of the text
  – Impact on reading of other parts of the text

• **Microstructure changes**
  – Don’t change the gist of the text
  – Are isolated in impact
Meaning Changes

• These are the focus of NLG research in
  – Content Determination
  – Text Structuring
The State of the Art and Where We Might Go

• Existing tools are concerned with surface revisions, and even then primarily with formal changes.
• But: we can conceive of machine assistance being provided for every aspect of revision.
• We can also conceive of machine assistance being provided for other stages of the writing process.

Figure 1. A Taxonomy of Revision Changes
Overview

• Introduction: The Need
• Spell Checking
• Grammar Checking
• Helping Non-Native Speakers
• Beyond Spelling and Grammar Checking
• Conclusions
Conclusions

- Current technology only scratches the surface in terms of the kinds of support we would like to give to authors
- Many aspects of NLP technology can be pressed into service to support authors
- NLG techniques provide a rich source of ideas for how to build symbiotic systems that take advantage of the knowledge and capabilities of both human and machine
