ULTRAFILTERS, FINITE COPRODUCTS AND LOCALLY CONNECTED CLASSIFYING TOPOSES

RICHARD GARNER

Abstract. We prove a single category-theoretic result encapsulating the notions of ultrafilters, ultrapower, tensor product of ultrafilters and Blass’s category of ultrafilters $UF$. The result states that the category $\mathcal{F}(\mathcal{E}, \mathcal{E})$ of finite-coproduct-preserving endofunctors of $\mathcal{E}$ is equivalent to the presheaf category $[\mathcal{U}, \mathcal{E}]$. We then generalise this result in two directions, yielding, in the end, an equivalence $\mathcal{F}(\mathcal{E}, \mathcal{E}) \simeq [\mathcal{U}, \mathcal{E}]$ for any extensive category $\mathcal{E}$ and locally connected Grothendieck topos $\mathcal{E}$. These generalisations allow us to reconstruct both ultraproducts and indexed sum of ultrafilters, and to draw connections with a range of prior work including Makkai’s ultracategories.

Our final main result uses the previous ones to construct the locally connected classifying topos of a small De Morgan pretopos $\mathcal{C}$: that is, the universal locally connected Grothendieck topos admitting a pretopos morphism from $\mathcal{C}$. The existence of this is known from work of Funk, but the description is inexplicit; ours, by contrast, is quite concrete. We also draw connections to the toposes of types studied by Joyal, Reyes, Makkai, Pitts and others.

1. Introduction

Ultrafilters are important in many areas of mathematics, from Ramsey theory, to topological dynamics, to universal algebra and model theory; see [7] for an overview. Around the notion of ultrafilter is a circle of associated concepts: the ultrapower of a set by an ultrafilter, or more generally, the ultraproduct of a family of sets [16]; the tensor product of ultrafilters [26] and the more general indexed sum; and the Rudin–Keisler partial ordering on ultrafilters, first written down by Blass in [5] and immediately enhanced to a category of ultrafilters.

These concepts invite a category-theoretic treatment. In fact, various authors have gone further in giving categorical explanations for some of the notions involved, showing that they arise as inevitable consequences of basic concepts of category theory. A key object of focus has been the endofunctor $\beta: \mathcal{E} \to \mathcal{E}$ for which $\beta X$ is the set of ultrafilters on $X$. This $\beta$ is not just an endofunctor but a monad on $\mathcal{E}$, whose algebras are the compact Hausdorff spaces. In [29], Kennison and Gildenhuys characterised it as the codensity monad of the inclusion $I: \text{FinSet} \hookrightarrow \mathcal{E}$. This means that it is the reflection of $I$ along the “semantics” functor sending a monad on $\mathcal{E}$ to its concrete category of algebras.

Later, in [9], Börger gave a different characterisation of $\beta$ as the terminal finite-coproduct-preserving endofunctor of $\text{Set}$, with this terminality inducing the monad structure automatically. Most recently, in [31] Leinster gave a detailed treatment and new perspectives on [29]'s result, and extended it to a codensity characterisation of [28]'s ultraproduct monad on the arrow category $\text{Set}^2$.

This paper is a further contribution in this vein. We give a single category-theoretic result from which ultrafilters, ultrapowers, the tensor product of ultrafilters, and Blass's category $\text{UF}$ of ultrafilters, together with their interrelations, all flow naturally. This result, proved as Theorem 13 and Corollary 14 below, is:

**Theorem.** The category $\text{FC}(\text{Set}, \text{Set})$ of finite-coproduct-preserving endofunctors of $\text{Set}$ is equivalent to the functor category $[\text{UF}, \text{Set}]$. Under this equivalence, the ultrapower functor $(\cdot)^U$ corresponds to the representable functor at the ultrafilter $U$.

One way of seeing this result is that once we know what a finite coproduct-preserving endofunctor of $\text{Set}$ is, everything else is forced. The ultrapower endofunctors of $\text{Set}$ arise as the small-projectives in $\text{FC}(\text{Set}, \text{Set})$, and the full subcategory they span is equivalent to $\text{UF}^{\text{op}}$. Moreover, as we will see in Proposition 16, the composition monoidal structure on $\text{FC}(\text{Set}, \text{Set})$ restricts to this subcategory, and in this way recovers the tensor product of ultrafilters.

One thing this theorem does not capture is the notion of ultraproduct. For this, we require a generalisation of the theorem dealing with ultrafilters not on sets, but on objects of a category $\mathcal{C}$ which is extensive [12], meaning that it has well-behaved finite coproducts. In this context, an ultrafilter on $X \in \mathcal{C}$ can be defined as an ultrafilter on the Boolean algebra of coproduct summands of $X$, giving rise to a category $\text{UF}_\mathcal{C}$ generalising Blass' $\text{UF}$. We now obtain the following natural generalisation of our main theorem, to be proved as Theorem 22:

**Theorem.** Let $\mathcal{C}$ be extensive. The category $\mathcal{F}\mathcal{C}(\mathcal{C}, \text{Set})$ of finite-coproduct-preserving functors from $\mathcal{C}$ to $\text{Set}$ is equivalent to the functor category $[\text{UF}_\mathcal{C}, \text{Set}]$.

As we will see in Section 4.2, we may recapture ultraproducts from this theorem by taking $\mathcal{C} = \text{Set}^X$, yielding an equivalence $[\text{UF}_{\text{Set}^X}, \text{Set}] \simeq \mathcal{F}\mathcal{C}(\text{Set}^X, \text{Set})$; now the ultraproduct functors $\Pi_U : \text{Set}^X \to \text{Set}$ correspond under this equivalence to suitable representable functors in $[\text{UF}_{\text{Set}^X}, \text{Set}]$.

A second application, described in Section 4.3, takes $\mathcal{C}$ to be the classifying Boolean pretopos of a theory $\mathcal{T}$ of classical first-order logic. In this case, ultrafilters on $A \in \mathcal{C}$ correspond to model-theoretic types in context $A$, and our result allows us to reconstruct a known categorical treatment of these [35]. Indeed, by the classifying property of $\mathcal{C}$, models of $\mathcal{T}$ correspond to pretopos morphisms $\mathcal{C} \to \text{Set}$. As pretopos morphisms preserve finite coproducts, the theorem thereby associates to each $\mathcal{T}$-model $M$ a functor $\text{UF}_\mathcal{C} \to \text{Set}$—whose values pick out the sets of elements in $M$ that realise each model-theoretic type.

Our main theorem can be generalised further by varying the codomain category as well as the domain category. Recall that a Grothendieck topos is the category of sheaves on a small site, and that a Grothendieck topos $\mathcal{E}$ is locally connected when the left adjoint $\Delta : \text{Set} \to \mathcal{E}$ of its global sections functor $\Gamma = \mathcal{E}(1, -) : \mathcal{E} \to \text{Set}$ has a further left adjoint $\pi_0 : \mathcal{E} \to \text{Set}$. The second generalisation of our main theorem, to be proved as Theorem 26 below, is now:
Theorem. Let $\mathcal{C}$ be extensive and $\mathcal{E}$ a locally connected Grothendieck topos. The category $\mathfrak{F}\mathcal{C}(\mathcal{C}, \mathcal{E})$ of finite-coproduct-preserving functors from $\mathcal{C}$ to $\mathcal{E}$ is equivalent to the functor category $[\mathcal{U}\mathfrak{F}_{\mathcal{C}}, \mathcal{E}]$.

One application of this theorem, described in Section 5.2, allows us to reconstruct the indexed sum of ultrafilters. For any sets $X$ and $Y$, our theorem yields an equivalence $\mathfrak{F}\mathcal{C}(\text{Set}^X, \text{Set}^Y) \simeq [\mathcal{U}\mathfrak{F}_{\text{Set}}^X, \text{Set}^Y]$, and we define a generalized ultraproduct functor $\mathcal{E}^X \to \text{Set}^Y$ to be one that corresponds under this equivalence to a pointwise representable functor $\mathcal{U}\mathfrak{F}_{\text{Set}}^X \to \text{Set}^Y$. Such functors have a representation as ultraspans: that is, as diagrams

$$
\begin{array}{ccc}
X & \xrightarrow{f} & M \\
\downarrow & & \downarrow (g, U) \\
Y
\end{array}
$$

with left leg a function $f$ and right leg a function $g$ endowed with an ultrafilter $U_y$ on each fibre $g^{-1}y$. Moreover, it turns out that generalised ultraproduct functors are closed under composition, so inducing a composition law on ultraspans (1.1) which encodes perfectly the indexed sum of ultrafilters.

Another potential application of the above theorem, sketched in Section 5.3, is to Makkai’s ultracategories [36]. An ultracategory is a category $\mathcal{C}$ endowed with abstract ultraproduct functors $\Pi_U: \mathcal{C}^X \to \mathcal{C}$ together with interpretations for any “definable map between ultraproducts”—the ultramorphisms of [36]. The key example of an ultracategory is the category of models of a coherent theory $T$ in intuitionistic first-order logic, and [36]’s main result shows that, to within Morita equivalence, $T$ can be reconstructed from its ultracategory of models.

We expect to relate ultracategories to our main result via the machinery of enriched categories [27, 41]. We have calculated far enough to convince ourselves that categories endowed with abstract ultraproduct functors can be identified with certain categories enriched over the bicategory $\mathfrak{F}\mathcal{C}_{\text{Set}}$ of finite-coproduct-preserving functors between powers of $\text{Set}$ which admit certain copowers (a kind of enriched colimit). The key point is that, in proving this, we exploit the equivalences $\mathfrak{F}\mathcal{C}(\text{Set}^X, \text{Set}^Y) \simeq [\mathcal{U}\mathfrak{F}_{\text{Set}}^X, \text{Set}^Y]$ established above. We will develop this line of thought further in future work.

Our final main result exploits the preceding theorems to construct the locally connected classifying topos of a suitable pretopos $\mathcal{C}$; that is, the universal locally connected Grothendieck topos admitting a pretopos morphism from $\mathcal{C}$. The existence of such locally connected classifying toposes follows from [17]; however, the existence proof given there is somewhat inexplicit. We will improve on this by showing that any small pretopos satisfying the De Morgan property (recalled in Definition 37 below) has a locally connected classifying topos given by the topos of sheaves on $\mathcal{U}\mathfrak{F}_{\mathcal{C}}$ for a certain Grothendieck topology, related to one found in [25]. Our final main result, proved as Theorem 41 below, is thus:

Theorem. Let $\mathcal{C}$ be a small De Morgan pretopos. The topos $\mathcal{S}h(\mathcal{U}\mathfrak{F}_{\mathcal{C}})$ is a locally connected classifying topos for $\mathcal{C}$, and is itself De Morgan.

The locally connected classifying topos of a pretopos is closely related to Makkai’s topos of types [35] of a pretopos, and similar such toposes studied
by Joyal and Reyes [25] and Pitts [39]. Makkai’s topos of types is a topos of sheaves on the category of prime filters of a pretopos, rather than the category of ultrafilters, and with respect to a Grothendieck topology which is qualitatively different in nature. While we discuss briefly the similarities and differences between the constructions, in particular comparing their universal properties, we will, once again, leave a more detailed comparison to future work.

2. Background

2.1. Ultrafilters, ultraproducts and ultrapowers. In this section, we recall the notions that our main theorem is designed to capture and their interrelations with each other. Before starting on this, we first establish some notational conventions for indexed families which will be used throughout the paper.

Definition 1. Let \( Y = (Y(x) \mid x \in X) \) be an \( X \)-indexed family of sets. We write \( (\Sigma_{x \in X} Y(x)) \) or more briefly \( X.Y \) for the indexed sum of this family, that is, the set of pairs \( \{(x,y) : x \in X, y \in Y(x)\} \). We write \( \pi_Y : X.Y \to X \) for the first projection map, and call this map the display family associated to \( Y \). We also write \( (\Pi_{x \in X} Y(x)) \) for the indexed product of the \( Y(x) \)'s: that is, the set of functions \( f : X \to X.Y \) which are sections of \( \pi_Y : X.Y \to X \).

More generally, a display family over \( X \) is any function \( \pi : E \to X \), and the \( X \)-indexed family associated to \( \pi \) is the family of fibres \( \pi^{-1}(x) \mid x \in X \). As is well known, the passage between \( X \)-indexed families and display families over \( X \) underlies an equivalence of categories

\[
\text{Set}^X \cong \text{Set}/X.
\]

This equivalence and its generalisations will play an important role in this paper.

Definition 2. An ultrafilter on a set \( X \) is a Boolean algebra homomorphism \( u : P(X) \to 2 \). Most often, we describe \( u \) by specifying the subset \( U = u^{-1}(\top) \) of \( P(X) \); so an ultrafilter is equally a collection \( U \) of subsets of \( X \) such that:

(i) \( X \in U \), and \( U \cap V \in U \iff (U \in U \text{ and } V \in U) \);
(ii) \( \bot \notin U \), and \( U \cup V \in U \iff (U \in U \text{ or } V \in U) \).

Equivalently, we may replace condition (ii) with:

(ii)' \( U \in U \iff X \setminus U \notin U \).

We write \( \beta X \) for the set of ultrafilters on the set \( X \).

The principal ultrafilter at \( x \in X \) is \( \uparrow x = \{ U \subseteq X : x \in U\} \). These are the only ultrafilters we can write down explicitly; indeed, the existence of non-principal ultrafilters is a choice principle, slightly weaker than the axiom of choice.

It is often useful to view ultrafilters as generalised quantifiers. Given a predicate \( \varphi(x) \) depending on \( x \in X \) and an ultrafilter \( U \) on \( X \), we write \( (\forall_U x \in X) \varphi(x) \) to indicate that \( \{ x \in X : \varphi(x) \} \in U \) and say that “for \( U \)-almost all \( x \), \( \varphi(x) \) holds”.

Definition 3. Let \( U \in \beta X \). If \( Y \) is a set, then the ultrapower \( Y^U \) is the set of \( =_U \)-equivalence classes of partial functions \( X \to Y \) defined on a set in \( U \), where

\[
f =_U g \iff (\forall_U x \in X) f(x) \equiv g(x).
\]
Here we write $f(x) \equiv g(x)$ to mean “$f$ and $g$ are defined at $x$ and are equal”.

More generally, if $Y$ is an $X$-indexed family of sets, then the ultraprodut
$(\prod x \in X) Y(x)$ is the set of $=_{\mathfrak{U}}$-equivalence classes of partial sections, defined on
a set in $\mathfrak{U}$, of $\pi_Y: X \cdot Y \to X$. Note that $Y^\mathfrak{U} = (\prod x \in X) Y$.

Alternatively, we can describe ultraproducts and ultrapowers as the following
colimits of function spaces, wherein we view $\mathfrak{U}$ as a poset ordered by inclusion.
This description makes it clear that ultraproduct and ultrapower are functores
$(-)^\mathfrak{U}: \text{Set} \to \text{Set}$ and $\prod: \text{Set}^X \to \text{Set}$ respectively.
\[
Y^\mathfrak{U} = \text{colim}_{U \in \mathfrak{U}} Y^U
\]
(2.3)
$(\prod x \in X) Y(x) = \text{colim}_{U \in \mathfrak{U}} (\prod x \in U) Y(x).

2.2. The category of ultrafilters. Given ultrafilters $\mathfrak{U}$ on $X$ and $\mathcal{V}$ on $Y$, we say
that $f: X \to Y$ is continuous if $V \in \mathcal{V}$ implies $f^{-1}(V) \in \mathfrak{U}$. By axiom (ii)$'$ and
the fact that $f^{-1}$ preserves complements, this is equally the condition that
\[
V \in \mathcal{V} \iff f^{-1}(V) \in \mathfrak{U}.
\]
(2.4)

The continuous maps play an important role in two natural categories of
ultrafilters, originally defined in [26, 30] in the more general context of filters.

**Definition 4.** The category $\mathfrak{U} \mathcal{E}$ of ultrafilters has pairs $(X \in \text{Set}, \mathfrak{U} \in \beta X)$ as
objects, and as maps $(X, \mathfrak{U}) \to (Y, \mathcal{V})$ the continuous maps $X \to Y$. The category
$\mathfrak{U} \mathcal{F}$ of ultrafilters has the same objects, and as morphisms $(X, \mathfrak{U}) \to (Y, \mathcal{V})$ the
$=_{\mathfrak{U}}$-equivalence classes of partial continuous maps $X \to Y$ defined on a set in $\mathfrak{U}$.

Our naming reflects that $\mathfrak{U} \mathcal{F}$ is the “good” category of ultrafilters and $\mathfrak{U} \mathcal{E}$ just
a preliminary step to get there; for indeed, $\mathfrak{U} \mathcal{F}$ arises by inverting the class $\mathcal{M}$
of continuous injections in $\mathfrak{U} \mathcal{E}$. The proof of this fact given below mirrors that
given in [6, Theorem 16] for the category of filters; in its statement, $\iota: \mathfrak{U} \mathcal{E} \to \mathfrak{U} \mathcal{F}$
is the identity-on-objects functor taking $f$ to its $=_{\mathfrak{U}}$-equivalence class.

**Proposition 5.** $\iota: \mathfrak{U} \mathcal{E} \to \mathfrak{U} \mathcal{F}$ exhibits $\mathfrak{U} \mathcal{F}$ as $\mathfrak{U} \mathcal{E}[\mathcal{M}^{-1}]$.

**Proof.** Each map in $\mathcal{M}$ factors as an isomorphism followed by a continuous subset
inclusion; whence $\mathfrak{U} \mathcal{E}[\mathcal{M}^{-1}] = \mathfrak{U} \mathcal{E}[\mathcal{J}^{-1}]$ where $\mathcal{J}$ is the class of all continuous subset
inclusions in $\mathfrak{U} \mathcal{E}$. It is easy to see that any map in $\mathcal{J}$ is of the form
\[
m_{WY} : (W, \mathcal{V}|_W) \to (Y, \mathcal{V})
\]
where $W \in \mathcal{V}$ and $\mathcal{V}|_W = \{U \subseteq W : U \in \mathcal{V}\}$. Such maps are stable under composition and contains the identities. Moreover, given a map (2.5) and
$f: (X, \mathfrak{U}) \to (Y, \mathcal{V})$ in $\mathfrak{U} \mathcal{E}$, we have a commuting square (in fact a pullback) in
$\mathfrak{U} \mathcal{E}$ of the form
\[
\begin{array}{ccc}
(f^{-1}(W), \mathfrak{U}|_{f^{-1}W}) & \to & (W, \mathcal{V}|_W) \\
\downarrow m_{f^{-1}W,X} & & \downarrow m_{WY} \\
(X, \mathfrak{U}) & \overset{f}{\longrightarrow} & (Y, \mathcal{V})
\end{array}
\]
since $f^{-1}(W) \in \mathfrak{U}$ by continuity of $f$. So $\mathcal{J}$ satisfies the first three of the four
axioms for a calculus of right fractions [18], and satisfies the final one trivially.
since it is a class of monomorphisms. We may thus describe the localisation $\mathcal{U}E[\exists^{-1}]$ as follows. Objects are those of $\mathcal{U}E$, and maps $(X, \mathcal{U}) \to (Y, \mathcal{V})$ are spans in $\mathcal{U}E$ as left below, with two such spans being identified if they can be completed to a commuting diagram as to the right.

$$
\begin{array}{ccc}
(U, \mathcal{U}|_U) & \xrightarrow{m_{U \times X}} & (X, \mathcal{U}) \\
\downarrow f & & \downarrow \leftarrow & \downarrow g \\
(Y, \mathcal{V}) & \xrightarrow{m_{Y \times V}} & (V, \mathcal{U}|_V)
\end{array}
$$

Clearly these maps correspond to $=_\mathcal{U}$-equivalence classes of partial continuous functions; moreover, under this identification, the identity-on-objects functor $\mathcal{U}E \to \mathcal{U}E[\exists^{-1}]$ sends $f$ to $(1, f)$, whence $\mathcal{U}E \cong \mathcal{U}E[\exists^{-1}]$ under $\mathcal{U}E$ as desired. \qed

2.3. Tensor product and indexed sum of ultrafilters. The tensor product of ultrafilters is sometimes called the product. It is most easily expressed in terms of generalised quantifiers.

**Definition 6.** Let $\mathcal{U}$ and $\mathcal{V}$ be ultrafilters on $X$ and $Y$. The **tensor product** $\mathcal{U} \otimes \mathcal{V}$ is the unique ultrafilter on $X \times Y$ which for all predicates $\varphi$ on $X \times Y$ satisfies:

$$
(\forall_{U \otimes V}(x,y) \in X \times Y) \varphi(x,y) \iff (\forall_U x \in X)(\forall_V y \in Y) \varphi(x,y).
$$

Instantiating $\varphi$ at the characteristic predicates of subsets $A \subseteq X \times Y$ yields the following explicit formula, wherein we write $x^* A$ for $\{y \in Y : (x, y) \in A\}$:

$$
\mathcal{U} \otimes \mathcal{V} = \{A \subseteq X \times Y : \{x \in X : x^* A \in \mathcal{V}\} \in \mathcal{U}\}.
$$

Using this formula, we see that if $f : (X, \mathcal{U}) \to (X', \mathcal{U}')$ and $g : (Y, \mathcal{V}) \to (Y', \mathcal{V}')$ in $\mathcal{U}E$ then also $f \times g : (X \times Y, \mathcal{U} \otimes \mathcal{V}) \to (X' \times Y', \mathcal{U}' \otimes \mathcal{V}')$. So tensor product of ultrafilters gives a monoidal structure on $\mathcal{U}E$, with as unit the unique ultrafilter on the one-element set. Since maps in $\mathcal{M}$ are closed under the binary tensor, this monoidal structure descends along $\iota$ to one on $\mathcal{U}F$.

The following result, which is a special case of [16, Theorem 1.10], describes the interaction of the tensor product with ultrapowers and ultraproducts. Observe that (2.7) is precisely the “proof-relevant” form of (2.6).

**Proposition 7.** Given $\mathcal{U} \in \beta X$ and $\mathcal{V} \in \beta Y$ and an $X \times Y$-indexed family of sets $Z$, curryng of functions induces an isomorphism of ultraproducts

$$
(\Pi_{U \otimes V}(x, y) \in X \times Y) Z(x, y) \cong (\Pi_{U} x \in X)(\Pi_{V} y \in Y) Z(x, y)
$$

giving, when $Z$ is a constant family, isomorphisms $Z^{U \otimes V} \cong (Z^V)^U$.

A more general construction on ultrafilters is that of indexed sum.

**Definition 8.** Let $\mathcal{U}$ be an ultrafilter on $X$ and, for each $x \in X$, let $\mathcal{V}(x)$ be an ultrafilter on $Y(x)$. The **indexed sum** $(\Sigma_{x \in X}) \mathcal{V}(x)$ or $\mathcal{U} \uplus \mathcal{V}$ is the unique ultrafilter on $(\Sigma x \in X) Y(x) = X \hat{\times} Y$ which for all predicates $\varphi$ on $X \hat{\times} Y$ satisfies

$$
(\forall_{U \uplus V}(x,y) \in X \hat{\times} Y) \varphi(x,y) \iff (\forall_U x \in X)(\forall_V y \in Y(x)) \varphi(x,y).
$$
Note that when \( Y \) and \( V \) are constant families, we have \((\sum_{x \in X} \mathcal{V}) = \mathcal{U} \otimes \mathcal{V}\), so that indexed sum really does generalise tensor product. As before, we can obtain an explicit formula for indexed sum by instantiating at the characteristic functions of predicates, and can derive the corresponding “proof relevant” version of the formula; this is now the general case of [16, Theorem 1.10].

**Proposition 9.** Given \( \mathcal{U} \in \beta X \) and \( \mathcal{V} \in (\Pi_{x \in X} \beta(Y(x))) \) and an \( X.Y \)-indexed family of sets \( Z \), currying of functions induces an isomorphism of ultraproducts

\[
(\Pi_{x \in X} (\Pi_{y \in Y} Z(x, y))) \cong (\Pi_{x \in X} (\Pi_{y \in Y(x)} y \in Y(x))) Z(x, y).
\]

### 3. The main theorem

In this section, we prove our main theorem. This makes essential use of Börger’s characterisation [9] of the ultrafilter endofunctor, so we begin by recalling this.

#### 3.1. Börger’s theorem

If \( u: \mathcal{P} X \to 2 \) is a Boolean algebra homomorphism and \( f: X \to Y \), then \( u \circ (f^{-1}): \mathcal{P} Y \to \mathcal{P} X \to 2 \) is again a homomorphism, called the pushforward of \( u \) along \( f \). Identifying \( u \) with the corresponding \( \mathcal{U} \subseteq \mathcal{P} X \), its pushforward along \( f \) is given by:

\[
f_!(\mathcal{U}) = \{ V \subseteq Y : f^{-1}(V) \subseteq \mathcal{U} \}.
\]

**Definition 10.** The ultrafilter endofunctor \( \beta: \text{Set} \to \text{Set} \) has action on objects \( X \mapsto \beta X \) and action on morphisms \( \beta f: \beta X \to \beta Y \) given by \( \mathcal{U} \mapsto f_!(\mathcal{U}) \).

In [9] Börger characterises \( \beta \) as terminal in the category \( \mathcal{F}\mathcal{C}(\text{Set}, \text{Set}) \) of finite-coproduct-preserving endofunctors of \( \text{Set} \). In reproducing the proof, and subsequently, we will use the following lemma, whose proof is either an easy exercise for the reader, or a consequence of the more general Lemma 19 below. In the statement, we call a natural transformation \( \alpha: F \Rightarrow G: \mathcal{E} \to \mathcal{D} \) monocartesian if the naturality square of \( \alpha \) at any monomorphism \( f: X \to Y \) is a pullback.

**Lemma 11.** Let \( G: \text{Set} \to \text{Set} \) preserves finite coproducts and let \( \alpha: F \Rightarrow G \).

(i) \( G \) preserves monomorphisms and pullbacks along monomorphisms;

(ii) \( F \) preserves finite coproducts if and only if \( \alpha \) is monocartesian.

**Theorem 12.** [9, Theorem 2.1] \( \beta \) is terminal in \( \mathcal{F}\mathcal{C}(\text{Set}, \text{Set}) \).

**Proof.** For an injection \( f: X \to Y \), the map \( \beta f: \beta X \to \beta Y \) is also injective with \( \text{im } \beta f = \{ V \in \beta Y : f(X) \subseteq V \} \).

Indeed, since \( f \) is injective, \( f^{-1}: \mathcal{P} Y \to \mathcal{P} X \) is surjective and so \( \beta f = (-) \circ (f^{-1}) \) is injective. As for its image: each \( \mathcal{U} \in \beta X \) contains \( X = f^{-1}(f(X)) \), so by (3.1) each \( f_!(\mathcal{U}) \) contains \( f(X) \). Conversely, if \( V \in \beta Y \) contains \( f(X) \), then \( \mathcal{U} = \{ U \subseteq X : f(U) \subseteq V \} \) is an ultrafilter on \( X \) with \( f_!(\mathcal{U}) = V \).

We first use this to show \( \beta \in \mathcal{F}\mathcal{C}(\text{Set}, \text{Set}) \). Clearly \( \beta(\emptyset) = \emptyset \); while if we have a coproduct \( y_1: Y_1 \to Y \leftarrow Y_2: y_2 \), then the maps \( \beta y_1: \beta Y_1 \to \beta Y \leftarrow \beta Y_2 \) are each injective with as images the sets \( A = \{ U \in \beta Y : \text{im } y_1 \subseteq U \} \) and \( B = \{ U \in \beta Y : \text{im } y_2 \subseteq U \} \). Since \( \text{im } y_1 \) and \( \text{im } y_2 \) partition \( Y \), each \( \mathcal{U} \in \beta Y \) lies in exactly one of \( A \) or \( B \) whence \( (\beta y_1, \beta y_2) \) is again a coproduct cone.
We now show \( \beta \) is terminal in \( \mathfrak{S} \mathfrak{C}(\text{Set}, \text{Set}) \). Given \( T \in \mathfrak{S} \mathfrak{C}(\text{Set}, \text{Set}) \) and \( x \in TX \), define the \emph{type} of \( x \) as the ultrafilter on \( X \) given by:

\[
\tau_X(x) = \{ U \subseteq X : x \text{ factors through the monic } FU \rightarrow FX \}.
\]

Here, \( FU \rightarrow FX \) is the \( F \)-image of the inclusion \( U \subseteq X \), and so monic by Lemma 11. \( \tau_X(x) \) satisfies axiom (i) for an ultrafilter since \( F \) preserves pullbacks of monics, and satisfies (ii)' as \( FU \rightarrow FX \leftarrow F(X \setminus U) \) is the \( F \)-image of a coproduct diagram and so itself a coproduct.

So we have functions \( \tau_X : TX \rightarrow \beta X \). To verify their naturality in \( X \) we must show for any \( x \in TX \) and \( f : X \rightarrow Y \) that \( \tau_Y(Ff(x)) = f(\tau_X(x)) \). So for any \( V \subseteq Y \), we must show \( Ff(x) \in FY \) factors through \( FY \rightarrow FY \) if and only if \( x \in FX \) factors through \( Ff^{-1}(V) \rightarrow FX \); which is so because \( F \) preserves the pullback of \( V \rightarrow Y \) along \( f : X \rightarrow Y \) by Lemma 11. So we have \( \tau : T \Rightarrow \beta \).

Finally, we check uniqueness of \( \tau \). Any \( \sigma : T \Rightarrow \beta \) is monocartesian by Lemma 11; and so for each \( m : U \subseteq X \) the following square is a pullback:

\[
\begin{array}{ccc}
TU & \xrightarrow{Tm} & TX \\
\sigma_V \downarrow & & \downarrow \sigma_X \\
\beta U & \xrightarrow{\beta m} & \beta X.
\end{array}
\]

Thus, \( x \in TX \) factors through \( Tm \) if and only if \( \sigma_X(x) \) factors through \( \beta m \) which by (3.2) happens just when \( U \in \sigma_X(x) \). So \( \sigma_X(x) = \tau_X(x) \) as desired. \( \square \)

3.2. \textbf{The main theorem.} We now exploit Börger’s theorem to prove our main Theorem 13. In doing so, we make use of the well-known generalisation of (2.1) stating that any slice of a presheaf category is equivalent to a presheaf category.

Indeed, given \( X \in [A, \text{Set}] \), the \emph{category of elements} \( elX \) has as objects, pairs \((A, x, x \in A)\) and as morphisms \((A, x) \rightarrow (A', x')\), maps \( f : A \rightarrow A' \) in \( A \) such that \( x' = xf(x) \). The equivalence in question is now

\[
(3.3) \quad [elX, \text{Set}] \simeq [A, \text{Set}]/X,
\]

and is constructed by applying (2.1) componentwise as follows. Going from left to right, \( Y : elX \rightarrow \text{Set} \) is sent to \( \pi : fY \rightarrow X \) whose \( A \)-component is given by the first projection map \((\Sigma x \in X A)Y(A, x) \rightarrow X A\), and where the action of \( fY \) on maps is induced from those of \( X \) and \( Y \). Going from right to left, \( p : E \rightarrow X \) in \([A, \text{Set}]/X\) is sent to \( \hat{E} \) in \([elX, \text{Set}]\) with \( \hat{E}(A, x) = p^{-1}_A(x) \subseteq EA \) and action on maps inherited from \( E \). For a detailed proof of the equivalence, see for example [22, Proposition A1.1.7].

**Theorem 13.** The category \( \mathfrak{S} \mathfrak{C}(\text{Set}, \text{Set}) \) of finite coproduct-preserving endofunctors of \( \text{Set} \) is equivalent to \([\text{UF}, \text{Set}]\).

**Proof.** Note that \( T \in [\text{Set}, \text{Set}] \) preserves finite coproducts if and only if it admits a monocartesian transformation to \( \beta \), which is then necessarily unique. The “if” direction of this claim follows from Lemma 11; whereupon the “only if” direction and the unicity follow from Theorem 12. So we have an isomorphism of categories

\[
(3.4) \quad \mathfrak{S} \mathfrak{C}(\text{Set}, \text{Set}) \cong [\text{Set}, \text{Set}]/_{mc} \beta.
\]
where to the right we have the full, replete, subcategory \([\text{Set}, \text{Set}]/_{\text{mc}} \beta\) of \([\text{Set}, \text{Set}]/\beta\) on the monocartesian arrows.

Now, the full slice category \([\text{Set}, \text{Set}]/\beta\) is equivalent to \([\text{el} \beta, \text{Set}]\). Here, objects of \(\text{el} \beta\) are pairs \((X \in \text{Set}, \mathcal{U} \in \beta X)\), while maps \((X, \mathcal{U}) \to (Y, \mathcal{V})\) are functions \(f: X \to Y\) such that \(f(\mathcal{U}) = \mathcal{V}\). Comparing (2.4) with (3.1), these are exactly the continuous maps, so that \(\text{el} \beta \cong \mathcal{U} \mathcal{E}\) and (3.3) becomes an equivalence:

\[(3.5) \quad [\text{Set}, \text{Set}]/\beta \simeq [\mathcal{U} \mathcal{E}, \text{Set}].\]

An object \(\tau: T \Rightarrow \beta\) to the left of this equivalence lies in the full replete subcategory \([\text{Set}, \text{Set}]/_{\text{mc}} \beta\) just when for each monic \(f: X \to Y\) and \(\mathcal{U} \in \beta X\), the map on fibres \(\tau_X^{-1}(\mathcal{U}) \to \tau_Y^{-1}(f(\mathcal{U}))\) is an isomorphism. This is equally the condition that the corresponding \(\tau \in [\mathcal{U} \mathcal{E}, \text{Set}]\) to the right lies in the full, replete subcategory of functors which send the class \(\mathcal{M}\) of continuous injective functions to isomorphisms. By Proposition 5, this subcategory is isomorphic to \([\mathcal{U} \mathcal{F}, \text{Set}]\) via restriction along \(\iota: \mathcal{U} \mathcal{E} \to \mathcal{U} \mathcal{F}\). So (3.5) restricts to an equivalence \([\text{Set}, \text{Set}]/_{\text{mc}} \beta \simeq [\mathcal{U} \mathcal{F}, \text{Set}]\), and combining this with (3.4) yields the desired equivalence \(\mathfrak{F} \mathcal{C}(\text{Set}, \text{Set}) \simeq [\mathcal{U} \mathcal{F}, \text{Set}]\).

Chasing through the above equivalences, we see that for each \(A \in \mathfrak{F} \mathcal{C}(\text{Set}, \text{Set})\), the corresponding \(A: \mathcal{U} \mathcal{F} \to \text{Set}\) is defined on objects by

\[(3.6) \quad A(X, \mathcal{U}) = \{ x \in AX : \tau_X(x) = \mathcal{U} \} \cong \bigcap_{U \in \mathcal{U}} \text{im} \, AU \subseteq AX.\]

For its definition on morphisms, let the map \((X, \mathcal{U}) \to (Y, \mathcal{V})\) of \(\mathcal{U} \mathcal{F}\) be represented by the partial continuous \(f: X \to Y\) defined on \(U \in \mathcal{U}\). Then the induced function \(A(X, \mathcal{U}) \to A(Y, \mathcal{V})\) is defined by \(x \mapsto Af(x')\), where \(x' \in AU\) is the lifting of \(x\) through \(AU \to AX\) guaranteed by the fact that \(U \in \tau_X(x)\).

In the other direction, for any \(B: \mathcal{U} \mathcal{F} \to \text{Set}\), the corresponding finite-coproduct-preserving \(fB: \text{Set} \to \text{Set}\) is defined by

\[(3.7) \quad (fB)Y = \sum_{Y \in \beta Y} B(Y, \mathcal{V}) \quad \text{and} \quad (fB)f: (\mathcal{V}, a) \mapsto (f(\mathcal{V}), Af(a)).\]

3.3. Relation to ultrapowers and tensor products. We now show that both ultrapowers and the tensor product of ultrafilters arise naturally from the preceding equivalence. We begin with ultrapowers.

**Corollary 14.** Under the equivalence of Theorem 13, the representable functor \(\mathcal{U} \mathcal{F}(\cdot, (X, \mathcal{U}), -): \mathcal{U} \mathcal{F} \to \text{Set}\) corresponds to the ultrapower functor \((-)^{\mathcal{U}}: \text{Set} \to \text{Set}\).

**Proof.** Taking \(B\) to be \(y(X, \mathcal{U}) = \mathcal{U} \mathcal{F}((X, \mathcal{U}), -)\) in (3.7), we have that

\[(f y(X, \mathcal{U}))(X) = \sum_{\mathcal{V} \in \beta Y} \mathcal{U} \mathcal{F}((X, \mathcal{U}), (Y, \mathcal{V})).\]

An element of this set is a pair \(\mathcal{V} \in \beta Y\) together with an \(=_{\mathcal{U}}\)-equivalence class of continuous partial functions \(f: (X, \mathcal{U}) \to (Y, \mathcal{V})\) defined on a set in \(\mathcal{U}\). The continuity condition (2.4) forces \(V = f(\mathcal{U})\) and so this is equally a \(=_{\mathcal{U}}\)-equivalence class of partial functions \(f: X \to Y\) defined on a set in \(\mathcal{U}\); thus an element of the ultrapower \(Y^{\mathcal{U}}\). This proves that \(f y(X, \mathcal{U}) \cong (-)^{\mathcal{U}}\) as desired. \(\square\)

As remarked in the introduction, we can use this result to recover the category \(\mathcal{U} \mathcal{F}\) from \(\mathfrak{F} \mathcal{C}(\text{Set}, \text{Set})\). Recall that an object \(X\) of a category \(\mathcal{E}\) is small-projective if the hom-functor \(\mathcal{E}(X, -): \mathcal{E} \to \text{Set}\) preserves all small colimits.
Corollary 15. The category \( \mathbb{U}^\text{op} \) is equivalent to the full subcategory of \( \mathfrak{S}\mathfrak{E}(\text{Set}, \text{Set}) \) on the small-projectives.

Proof. For any locally small \( \mathcal{A} \), the small-projectives in \( [\mathcal{A}, \text{Set}] \) are precisely the retracts of representable functors; see, for example, [8, Lemma 6.5.10]. So if representables are closed under retracts, then \( \mathcal{A}^\text{op} \) is equivalent to the full subcategory of \( [\mathcal{A}, \text{Set}] \) on the small-projectives.

It thus suffices to show that representables in \( [\mathbb{U}, \text{Set}] \) are closed under retracts. But if \( i: A \to y_{(X,\mathbb{U})} \) and \( p: y_{(X,\mathbb{U})} \to A \) with \( pi = 1 \), then \( ip: y_{(X,\mathbb{U})} \to y_{(X,\mathbb{U})} \) is the image under \( y \) of an idempotent on \( (X,\mathbb{U}) \). Since by [5, Theorem 5], the only idempotents (indeed, the only endomorphisms) in \( \mathbb{U} \) are the identities, we thus have \( ip = 1 \) as well as \( pi = 1 \), so that \( A \cong y_{(X,\mathbb{U})} \) is again representable. \( \square \)

We now turn to the tensor product of ultrafilters. The category \( \mathfrak{S}\mathfrak{E}(\text{Set}, \text{Set}) \) has a monoidal structure given by composition, and transporting this across the equivalence of Theorem 13 yields a monoidal structure \( (I, \otimes) \) on \( [\mathbb{U}, \text{Set}] \).

Proposition 16. The representables in \( [\mathbb{U}, \text{Set}] \) are closed under the monoidal structure, and the induced monoidal structure on \( \mathbb{U} \) is that given by tensor product of ultrafilters.

Proof. The identity functor \( \text{Set} \to \text{Set} \) corresponds to the functor \( \mathbb{U} \to \text{Set} \) represented by the unique ultrafilter on a one-element set, which is the unit for the monoidal structure on \( \mathbb{U} \). On the other hand, if \( A, B \in [\mathbb{U}, \text{Set}] \) are represented by \( (X,\mathbb{U}) \) and \( (Y,\mathbb{V}) \) respectively, then by Theorem 13 we have \( fA \cong (–)^\mathbb{U} \) and \( fB \cong (–)^\mathbb{V} \), and so \( fA \otimes fB \cong (fY)^\mathbb{U} \otimes (fY)^\mathbb{V} \). It follows that \( A \otimes B \) is represented by \( (X \times Y, \mathbb{U} \otimes \mathbb{V}) = (X,\mathbb{U}) \otimes (Y,\mathbb{V}) \) in \( \mathbb{U} \). \( \square \)

The monoidal structure on \( [\mathbb{U}, \text{Set}] \) is easy to write down explicitly. As already noted, the unit \( I \) is the functor representable at the unique ultrafilter on the one-element set, while the binary tensor can be given as \( A \otimes B = fA \circ fB \), where \( fA \) is defined as in (3.7). This yields the formulae:

\[
I(X,\mathbb{U}) = \begin{cases} 1 & \text{if } \mathbb{U} \text{ is principal;} \\ 0 & \text{otherwise.} \end{cases}
\]

\[
(A \otimes B)(X,\mathbb{U}) = \sum_{Y \in B(x,\mathbb{U})} A(B(x,\mathbb{U}),\mathbb{V}).
\]

We have an alternative description of the binary tensor product by exploiting the fact that, since the composition product on \( \mathfrak{S}\mathfrak{E}(\text{Set}, \text{Set}) \) preserves colimits in its first variable, so too does the tensor product \( \otimes \) on \( [\mathbb{U}, \text{Set}] \):

\[
(A \otimes B)(X,\mathbb{U}) \cong \left( \left( f^{(Y,\mathbb{V})} A(Y,\mathbb{V}) \times y_{(Y,\mathbb{V})} \right) \mathbb{U} \right)(X,\mathbb{U})
\]

\[
\cong \sum_{Y \in B(x,\mathbb{U})} A(B(x,\mathbb{U}),\mathbb{V}).
\]

\[
\cong f^{(Y,\mathbb{V})} A(Y,\mathbb{V}) \times B(x,\mathbb{U})^\mathbb{V}.
\]

Compare this with the well-known substitution monoidal structure on \([\mathcal{F}, \text{Set}]\)—for \( \mathcal{F} \) the category of functions between finite cardinals—defined by:

\[
(A \otimes B)(m) = f^{n \in \mathcal{F}} A_n \times B(m^n).
\]
Remark 17. Given a monoidal category $\mathcal{V}$, one may consider categories enriched over $\mathcal{V}$ in the sense of [27]. A $\mathcal{V}$-enriched category $\mathcal{C}$ involves a set of objects $A, B, C, \ldots$ as usual, but instead of hom-sets of morphisms, one has hom-objects $\mathcal{C}(A, B)$ in $\mathcal{V}$, with composition and identity operations given now by maps in $\mathcal{V}$. If $\mathcal{C}$ is a $\mathcal{V}$-enriched category, then one can talk about the copower $\mathcal{V} \cdot A$ of an object $A \in \mathcal{C}$ by an object $V \in \mathcal{V}$. This is a kind of enriched colimit, characterised by natural isomorphisms $\mathcal{C}(\mathcal{V} \cdot A, B) \cong [V, \mathcal{C}(A, B)]$ in $\mathcal{V}$.

In [19], the author considered categories enriched over $[\mathcal{F}, \text{Set}]$ with the substitution monoidal structure, and showed that such $[\mathcal{F}, \text{Set}]$-categories admitting copowers by representables correspond to ordinary categories $\mathcal{C}$ admitting finite powers $(-)^n : \mathcal{C} \to \mathcal{C}$. Here, the $[\mathcal{F}, \text{Set}]$-category corresponding to $\mathcal{C}$ has the same objects as $\mathcal{C}$, and hom-objects given by $\mathcal{C}(A, B)(n) = \mathcal{C}(A^n, B)$.

The analogy between (3.8) and (3.9) suggests that something similar should be possible with $[\mathcal{UF}, \text{Set}]$ in place of $[\mathcal{F}, \text{Set}]$, and this is indeed so: categories enriched over $[\mathcal{UF}, \text{Set}]$ admitting copowers by representables correspond to ordinary categories $\mathcal{C}$ equipped with abstract ultrapower functors $(-)^U : \mathcal{C} \to \mathcal{C}$. The $[\mathcal{UF}, \text{Set}]$-category corresponding to such a $\mathcal{C}$ has hom-objects given by $\mathcal{C}(A, B)(X, U) = \mathcal{C}(A^U, B)$. The details of this will be left for future work, but we discuss an extension to categories endowed with abstract ultraproduct functors in Section 5.3 below.

4. First generalisation

In this section, we give our first generalisation of Theorem 13. This will show that, for any extensive category $\mathcal{C}$, there is an equivalence $\mathfrak{C}(\mathcal{C}, \text{Set}) \simeq [\mathcal{UF}_\mathcal{C}, \text{Set}]$ where $\mathcal{UF}_\mathcal{C}$ is a suitably defined category of ultrafilters on $\mathcal{C}$-objects. We then describe how this result captures the notion of ultraproduct, and how it reconstructs the categorical treatment in [35] of types in model theory.

4.1. Generalising the domain category. We begin by recalling from [12] that a category $\mathcal{C}$ with finite coproducts is extensive if for every $A, B \in \mathcal{C}$, the functor $+: \mathcal{C}/A \times \mathcal{C}/B \to \mathcal{C}/(A + B)$ is an equivalence of categories. Equally, by [12, Proposition 2.2], $\mathcal{C}$ is extensive just when it has pullbacks along coproduct coprojections, and, for every diagram

\[
\begin{array}{ccc}
A' & \xleftarrow{i'} & C' & \xrightarrow{j'} & B' \\
\downarrow{a} & & \downarrow{c} & & \downarrow{b} \\
A & \xrightarrow{i} & C & \xleftarrow{j} & B
\end{array}
\]

in which the bottom row is a coproduct diagram, the top row is a coproduct diagram if and only if the two squares are pullbacks.

Note the “if” direction says that binary coproducts in $\mathcal{C}$ are pullback-stable. In fact, a category with finite coproducts and pullbacks along their coprojections is extensive just when binary coproducts are pullback-stable and disjoint; see [12, Proposition 2.14]. Disjointness means that coproduct coprojections are monic, and the pullback of the two coprojections of a binary coproduct is initial.
This characterisation implies that any topos is extensive; see [22, Proposition A2.3.4 & Corollary A2.4.4]. In particular, $\mathbf{Set}$ is extensive, as is any presheaf category. Other examples of extensive categories include the categories of topological spaces, of small categories and of affine schemes.

Let us write $\sum_C(X)$ for the poset of coproduct summands of $X \in C$: that is, the poset of isomorphism-classes of coproduct coprojections with codomain $X$.

**Proposition 18.** If $C$ is extensive, then for each $X \in C$ the poset $\sum_C(X)$ is a Boolean algebra, and for each $f : X \to Y$, pullback along $f$ defines a Boolean algebra homomorphism $f^{-1} : \sum_C(Y) \to \sum_C(X)$.

**Proof.** Since binary coproducts in $C$ are stable under pullback, so are coproduct coprojections; since they are also composition-closed, each $\sum_C(X)$ has finite meets, and $f^{-1} : \sum_C(Y) \to \sum_C(X)$ is well-defined and finite-meet-preserving. Now any $Y_1 \to Y$ in $\sum_C(X)$ is part of a coproduct $Y_1 \to Y' \leftarrow Y_2$. Of course $Y_1 \cup Y_2 = \top_Y$ in $\sum_C(Y)$, and $Y_1 \cap Y_2 = \bot_Y$ by disjointness; so $\sum_C(X)$ has complements and so is a Boolean algebra. Further, $f^{-1} : \sum_C(Y) \to \sum_C(X)$ preserves these complements as binary coproducts are pullback-stable. □

A case worth noting is that where $C$ is Boolean extensive, meaning that every monic in $C$ is a coproduct coprojection; in this situation $\sum_C(X)$ coincides with the full subobject lattice $\text{Sub}_C(X)$, so that all subobject lattices in $C$ are Boolean algebras—whence the nomenclature. In particular, the category of sets is Boolean extensive, so that the following result is a generalisation of Lemma 11 above. In the last part of the statement, a natural transformation $\alpha$ is called sum-cartesian if its naturality square at every coproduct coprojection is a pullback.

**Lemma 19.** Let $C$ and $D$ be extensive, let $G : C \to D$ be finite-coproduct-preserving and let $\alpha : F \Rightarrow G : C \to D$.

(i) $G$ preserves both coproduct coprojections and pullbacks along such;
(ii) $F$ preserves finite coproducts just when $\alpha : F \Rightarrow G$ is sum-cartesian.

**Proof.** The first part of (i) is clear. For the second, any pullback along a coproduct coprojection in $C$ is the left square of a diagram like (4.1) in which both rows are coproducts. Applying $F$, both rows remain coproducts and so by extensivity of $D$, both squares remain pullbacks. As for (ii), given a coproduct diagram $i : A \to C \leftarrow B : j$ in $C$, we consider the diagram

$$
\begin{array}{cccccc}
FA & \xrightarrow{Fi} & FC & \xleftarrow{Fj} & FB \\
\downarrow{\alpha_A} & & \downarrow{\alpha_C} & & \downarrow{\alpha_B} \\
GA & \xrightarrow{Gi} & GC & \xleftarrow{Gj} & GB
\end{array}
$$

in $D$. The bottom row is a coproduct since $G$ preserves such; so, by extensivity of $D$, the top row is a coproduct (i.e., $F$ preserves finite coproducts) just when both squares are pullbacks (i.e., $\alpha$ is sum-cartesian). □

If $C$ is extensive, then we define an ultrafilter on $X \in C$ to be a Boolean algebra homomorphism $\sum_C(X) \to 2$; equivalently, a subset $\mathcal{U} \subseteq \sum_C(X)$ satisfying the analogue of conditions (i) and (ii) or (i) and (ii)' of Definition 2.
Like before, we write $\beta X$ for the set of ultrafilters on $X \in \mathcal{C}$. Since each $f^{-1}: \text{Sum}_\mathcal{C}(Y) \to \text{Sum}_\mathcal{C}(X)$ is a Boolean algebra homomorphism, precomposition with $f^{-1}$ yields a function $\beta f: \beta X \to \beta Y$; in this way, we define an ultrafilter functor $\beta: \mathcal{C} \to \text{Set}$.

**Proposition 20.** $\beta: \mathcal{C} \to \text{Set}$ is terminal in $\mathfrak{F}\mathcal{C}(\mathcal{C}, \text{Set})$.

**Proof.** The proof in Theorem 12 adapts without difficulty to show that $\beta: \mathcal{C} \to \text{Set}$ preserves finite coproducts. To show terminality in $\mathfrak{F}\mathcal{C}(\mathcal{C}, \text{Set})$, we suppose given $T \in \mathfrak{F}\mathcal{C}(\mathcal{C}, \text{Set})$. For any $X \in \mathcal{C}$ and $x \in TX$, we again define the type of $x$ to be:

$$\tau_X(x) = \{U \overset{m}{\to} X \in \text{Sum}_\mathcal{C}(X) : x \text{ factors through } FU \overset{f}{\to} FX\}.$$  

The same argument as before, but now exploiting Lemma 19 in place of Lemma 11, shows that this definition gives the values of a well-defined natural transformation $\tau: T \Rightarrow \beta: \mathcal{C} \to \text{Set}$, and that this $\tau$ is unique. $\square$

Like before, given objects $X, Y \in \mathcal{C}$ endowed with ultrafilters $\mathcal{U}$ and $\mathcal{V}$, we call $f: X \to Y$ continuous if for all $V \in \text{Sum}_\mathcal{C}(Y)$ we have $V \in \mathcal{V} \iff f^{-1}(V) \in \mathcal{U}$. More generally, a map $f: U \to Y$ defined on the domain of some $U \to X$ in $\mathcal{U}$ is continuous if $V \to Y \in \mathcal{V}$ just when $f^{-1}(V) \to U \to X \in \mathcal{U}$. Two partial maps defined on $U$ and $U'$ are $=_{\mathcal{U}}$-equivalent if their restrictions to some $W \subseteq U \cap U'$ in $\mathcal{U}$ coincide.

**Definition 21.** The category $\mathcal{U}\mathfrak{E}_\mathcal{C}$ has pairs $(X \in \mathcal{C}, \mathcal{U} \in \beta X)$ as objects, and as morphisms $(X, \mathcal{U}) \to (Y, \mathcal{V})$ the continuous maps $X \to Y$. The category $\mathcal{U}\mathcal{F}_\mathcal{C}$ has the same objects, and as morphisms $(X, \mathcal{U}) \to (Y, \mathcal{V})$ the $=_{\mathcal{U}}$-equivalence classes of partial continuous maps $X \to Y$ defined on the domain of some $U \to X$ in $\mathcal{U}$.

Writing $\mathcal{M}_\Sigma$ for the maps in $\mathcal{U}\mathfrak{E}_\mathcal{C}$ whose underlying map in $\mathcal{C}$ is a coproduct coprojection, we have as in Proposition 5, that $\mathcal{U}\mathcal{F}_\mathcal{C} \cong \mathcal{U}\mathfrak{E}_\mathcal{C}[\mathcal{M}_\Sigma^{-1}]$. Now transcribing the proof of Theorem 13 and Corollary 14, but exploiting Proposition 20 and Lemma 19 in place of Theorem 12 and Lemma 11, gives the following.

**Theorem 22.** Let $\mathcal{C}$ be extensive. The category $\mathfrak{F}\mathcal{C}(\mathcal{C}, \text{Set})$ of finite coproduct-preserving functors $\mathcal{C} \to \text{Set}$ is equivalent to $[\mathcal{U}\mathcal{F}_\mathcal{C}, \text{Set}]$. Under this equivalence, the representable presheaf at $(X, \mathcal{U}) \in \mathcal{U}\mathcal{F}_\mathcal{C}$ corresponds to the “ultrahom functor”

$$\mathcal{C}(X, -)\mathcal{U} = \text{colim}_{U \in \mathcal{U}} \mathcal{C}(U, -): \mathcal{C} \to \text{Set}.$$  

The formulae for the two directions of the equivalence $\mathfrak{F}\mathcal{C}(\mathcal{C}, \text{Set}) \simeq [\mathcal{U}\mathcal{F}_\mathcal{C}, \text{Set}]$ are once again given by (3.6) and (3.7).

**Example 23.** The category $\text{Stone}$ of Stone spaces is extensive and $\text{Sum}_{\text{Stone}}(X)$ is the Boolean algebra of clopen sets of $X$. It follows by Stone duality that ultrafilters on $X \in \text{Stone}$ corresponds exactly with points of $X$, so that the category $[\mathcal{U}\mathcal{F}_{\text{Stone}}, \text{Set}]$ has pointed Stone spaces $(X, x)$ as objects, and as maps $f: (X, x) \to (Y, y)$, germs at $x$ of point-preserving continuous functions $X \to Y$. Under the equivalence $[\mathcal{U}\mathcal{F}_{\text{Stone}}, \text{Set}] \cong \mathfrak{F}\mathcal{C}(\text{Stone}, \text{Set})$, the representable at $(X, x)$ corresponds to the functor which sends a Stone space $Y$ to the stalk at $x$ of the sheaf of continuous functions $X \to Y$. 

4.2. Relation to ultraproducts. We now explain how Theorem 22 allows us to reconstruct the notion of ultraproduct. Taking \( \mathcal{C} = \text{Set}^X \) therein yields the equivalence \([\Pi \mathcal{F}_{\text{Set}^X}, \text{Set}] \simeq \mathfrak{C}(\text{Set}^X, \text{Set})\), and we will obtain the ultraproduct functors as correlates to the right of suitable representable functors to the left.

Note first that, via (2.1), we have for any \( A \in \text{Set}^X \) that

\[
\text{Sum}_{\text{Set}^X}(A) \cong \text{Sum}_{\text{Set}^X}(\pi_A: X.A \to X) \cong \mathcal{P}(X.A),
\]

so that ultrafilters on \( A \in \text{Set}^X \) can be identified with ultrafilters on \( X.A \) in \( \text{Set} \). Under this identification, the ultrafilter \( \mathcal{U} \) on \( X.A \) corresponds to the ultrafilter \( \mathcal{U} = \{ U : U \in \mathcal{U} \} \) on \( A \) composed of the subobjects \( U \hookrightarrow A \) obtained by passing the subobjects \( U \hookrightarrow X.A \to X \) across the equivalence (2.1).

**Proposition 24.** Under the equivalence \([\Pi \mathcal{F}_{\text{Set}^X}, \text{Set}] \simeq \mathfrak{C}(\text{Set}^X, \text{Set})\), the representable functor at \((A \in \text{Set}^X, \mathcal{U} \in \beta(X.A))\) corresponds to the composite

\[
\text{Set}^X \xrightarrow{\text{Set}^X \pi_A} \text{Set}^X.A \xrightarrow{\Pi \mathcal{U}} \text{Set}. \tag{4.2}
\]

In particular, the representable at \((1, \mathcal{U})\) corresponds to \( \Pi \mathcal{U}: \text{Set}^X \to \text{Set} \).

**Proof.** From Theorem 22 and the above remarks, we know that \( y_{(A, \mathcal{U})} \) corresponds to the ultrahom functor \( \text{Set}^X(A, -)_{\mathcal{U}} \). We now calculate that:

\[
\text{Set}^X(A, Y)_{\mathcal{U}} = \text{colim}_{U \in \mathcal{U}} \text{Set}^X(U, Y)
\]

\[
\cong \text{colim}_{U \in \mathcal{U}} \text{Set}/X(U \to X.A \xrightarrow{\pi_A} X, X.Y \xrightarrow{\pi_Y} X)
\]

\[
\cong \text{colim}_{U \in \mathcal{U}} \text{Set}/X.A(U \to X.A, \pi_A^*(X.Y) \xrightarrow{\pi_A \pi_Y} X.A)
\]

\[
\cong \text{colim}_{U \in \mathcal{U}} (\Pi x \in U)Y(\pi_A(x)) = (\Pi x \in X.A)Y(\pi_A(x)),
\]

so that \( y_{(A, \mathcal{U})} \) corresponds to the composite (4.2) as desired. \( \Box \)

4.3. Relation to model theory. We now draw the link between Theorem 22 and the model theorist’s *types* by considering the *classifying Boolean pretopos* \( \mathfrak{C}(\mathbb{T}) \) of a (classical) first-order theory \( \mathbb{T} \). We begin by recalling some necessary definitions.

A *pretopos* is a category which is finitely complete, extensive and also Barr-exact [1], meaning that it has well-behaved quotients of equivalence relations. A pretopos is *Boolean* if it is so qua extensive category. There is a standard notion of model of a first-order theory \( \mathbb{T} \) in a Boolean pretopos \( \mathcal{C} \), and these comprise the objects of a category \( \mathbb{T}-\text{Mod}_e(\mathcal{C}) \) whose maps are elementary embeddings.

A Boolean pretopos is said to be *classifying* for a first-order theory \( \mathbb{T} \) if it contains a “generic \( \mathbb{T} \)-model”. To make this precise, recall that a *pretopos morphism* \( F: \mathcal{C} \to \mathcal{D} \) is a functor preserving finite limits, finite coproducts and regular epimorphisms. If \( \mathcal{C} \) and \( \mathcal{D} \) are Boolean then such an \( F \) also preserves \( \mathbb{T} \)-models and so induces a functor \( F_*: \mathbb{T}-\text{Mod}_e(\mathcal{C}) \to \mathbb{T}-\text{Mod}_e(\mathcal{D}) \). Writing \( \mathfrak{P}_{\text{top}}(\mathcal{C}, \mathcal{D}) \) for the category of pretopos morphisms and all natural transformations, we have:

**Definition 25.** A *classifying Boolean pretopos* for a first-order theory \( \mathbb{T} \) is a Boolean pretopos \( \mathfrak{C}(\mathbb{T}) \) endowed with a \( \mathbb{T} \)-model \( \mathcal{G} \in \mathbb{T}-\text{Mod}_e(\mathfrak{C}(\mathbb{T})) \) such that, for any Boolean pretopos \( \mathcal{D} \), the following functor is an equivalence:

\[
\mathfrak{P}_{\text{top}}(\mathfrak{C}(\mathbb{T}), \mathcal{D}) \to \mathbb{T}-\text{Mod}_e(\mathcal{D})
\]

\[
F \mapsto F_*(\mathcal{G}), \tag{4.3}
\]
To construct the classifying Boolean pretopos of a first-order theory $\mathbb{T}$, we first form its first-order syntactic category $\mathcal{E}_\mathbb{T}$ whose objects are “formal $\mathbb{T}$-definable sets” $\{ \bar{x} : \varphi(\bar{x}) \}$ (i.e., first-order formulae-in-context) and whose maps are $\mathbb{T}$-provably equivalence classes of $\mathbb{T}$-provably functional relations from $\{ \bar{x} : \varphi(\bar{x}) \}$ to $\{ \bar{y} : \psi(\bar{y}) \}$. The classifying Boolean pretopos $\mathcal{Cl}(\mathbb{T})$ is now obtained by freely adjoining finite coproducts and coequalisers of equivalence relations to $\mathcal{E}_\mathbb{T}$ while preserving its existing finite unions and image factorisations.

We will not describe the generic model $\mathbf{G} \in \mathbb{T}$-$\text{Mod}_e(\mathcal{Cl}(\mathbb{T}))$ explicitly; however, if we assume for simplicity that $\mathbb{T}$ is single-sorted, then part of the genericity is the fact that $\text{Sum}_{\mathcal{Cl}(\mathbb{T})}(G)$ is the Lindenbaum–Tarski algebra of $\mathbb{T}$-provable equivalence classes of $\mathbb{T}$-propositions with one free variable. More generally $\text{Sub}_{\mathcal{Cl}(\mathbb{T})}(G^n)$ is the corresponding Lindenbaum–Tarski algebra over $n$ free variables, so that an ultrafilter on $G^n \in \mathcal{Cl}(\mathbb{T})$ is a complete $n$-type of $\mathbb{T}$.

Now, since $\mathcal{D} = \text{Set}$ is a Boolean pretopos, we obtain from (4.3) and Theorem 22 a string of functors

$$\mathbb{T}$-$\text{Mod}_e(\text{Set}) \xrightarrow{\sim} \text{Pretop}(\mathcal{Cl}(\mathbb{T}), \text{Set}) \xrightarrow{\subseteq} \mathfrak{S}\mathcal{C}(\mathcal{Cl}(\mathbb{T}), \text{Set}) \xrightarrow{\sim} [\mathcal{U}\mathcal{F}_{\mathcal{Cl}(\mathbb{T})}, \text{Set}]$$

assigning to each (ordinary) $\mathbb{T}$-model $\mathbf{M}$ both a functor $M : \mathcal{Cl}(\mathbb{T}) \to \text{Set}$ and a functor $\tilde{M} : \mathcal{U}\mathcal{F}_{\mathcal{Cl}(\mathbb{T})} \to \text{Set}$. In this context, the passage from $M$ to $\tilde{M}$ was described by Makkai in [35], who also observed its model-theoretic import: it encodes the types realised by tuples of elements of the model $\mathbf{M}$.

Indeed, the pretopos morphism $M : \mathcal{Cl}(\mathbb{T}) \to \text{Set}$ corresponding to the model $\mathbf{M}$ sends $G$ to the underlying set $|M|$ of the model, sends $G^n$ to $|M|^n$ and sends $\varphi \in \text{Sum}_{\mathcal{Cl}(\mathbb{T})}(G^n)$ to the set $\{ \bar{m} \in |M|^n : \mathbf{M} \models \varphi(\bar{m}) \}$. Thus, by (3.6), the value of the corresponding $\tilde{M} \in [\mathcal{U}\mathcal{F}_{\mathcal{Cl}(\mathbb{T})}, \text{Set}]$ at a complete $n$-type $\mathfrak{U}$ is given by the set of $n$-tuples of elements of $\mathbf{M}$ which realise the type $\mathfrak{U}$:

$$\tilde{M}(X^n, \mathfrak{U}) = \{ \bar{m} \in |M|^n : \varphi \in \mathfrak{U} \iff \mathbf{M} \models \varphi(\bar{m}) \}$$

5. Second generalisation

In this section, we give our second generalisation of Theorem 13, which extends the first one to an equivalence $\mathfrak{S}\mathcal{C}(\mathcal{E}, \mathcal{E}) \simeq [\mathcal{U}\mathcal{F}_{\mathcal{E}}, \mathcal{E}]$, where $\mathcal{E}$ is extensive as before, and now $\mathcal{E}$ is any locally connected Grothendieck topos. We then use this result to reconstruct the indexed sum of ultrafilters, and in the process of doing so construct interesting and natural bicategories of ultramatrices and ultraspans. Finally, we describe how this relates to the ultracategories of [36].

5.1. Generalising the codomain category. A locally small category $\mathcal{E}$ is a Grothendieck topos if it is equivalent to the category of sheaves on a small site. Equivalently, by Giraud’s theorem, $\mathcal{E}$ is a Grothendieck topos just when it is finitely complete, Barr-exact and infinitary extensive with a small generating set.

In any Grothendieck topos $\mathcal{E}$, the functor $\Gamma = \mathcal{E}(1,-) : \mathcal{E} \to \text{Set}$ has a left adjoint $\Delta : \text{Set} \to \mathcal{E}$ which sends a set $X$ to the coproduct $\Sigma_{x \in X} 1$. We say that $\mathcal{E}$ is locally connected (or molecular [3]) if $\Delta$ has a further left adjoint $\pi_0 : \mathcal{E} \to \text{Set}$. For example, by [13, p.414, Ex. 7.6], the topos of sheaves on a space $X$ is locally connected just when $X$ is locally connected in the usual sense;
in this case, $\pi_0: \text{Sh}(X) \to \text{Set}$ sends a sheaf to the set of connected components of the corresponding étale space over $X$.

**Theorem 26.** Let $\mathcal{C}$ be extensive and $\mathcal{E}$ a locally connected Grothendieck topos. The category $\mathfrak{E}(\mathcal{C}, \mathcal{E})$ is equivalent to $[\mathbb{U}_{\mathcal{E}}, \mathcal{E}]$ via an equivalence whose two directions are given by the formulae (3.6) and (3.7).

In proving this, we require a straightforward generalisation of the equivalence $[\text{el} X, \text{Set}] \simeq [A, \text{Set}]/_X$ of (3.3) to an equivalence

$$(5.1) \quad [\text{el} X, \mathcal{E}] \simeq [A, \mathcal{E}]/\Delta X$$

for any Grothendieck topos $\mathcal{E}$. The generalisation makes use of the fact that $\mathcal{E}$ is infinitary extensive; this means that it has all small coproducts, and that for any set $X$, the coproduct functor $\Sigma: \coprod_{x \in X} (\mathcal{E}/A_x) \to \mathcal{E}/(\Sigma_{x \in X} A_x)$ is an equivalence of categories. Taking each $A_x$ to be terminal and using $\mathcal{E}/\mathcal{E}$, we deduce that

$$\Sigma: \mathcal{E}X \to \mathcal{E}/\Delta X$$

is an equivalence for any set $X$, with pseudoinverse given (necessarily) by pullback along the coproduct coprojections. By using this equivalence in place of (2.1), we may generalise (3.3) to the desired equivalence (5.1). Much as before, $Y \in [\text{el} X, \mathcal{E}]$ is sent to $\pi: \coprod Y \to \Delta X$ whose component $\pi_A: (\coprod Y)A \to \Delta XA$ is the coproduct of the family of maps $(Y(A, x) \to 1)_{x \in \Delta XA}$; while conversely, $p: E \to X$ in $[A, \mathcal{E}]/_X$ is sent to $E \in [\text{el} X, \mathcal{E}]$ wherein $E(A, x)$ is the pullback of $p_A: EA \to \Delta XA$ along $\Delta x: \Delta 1 \to \Delta XA$.

**Proof of Theorem 26.** Since $\pi_0: \Delta \dashv \Gamma: \mathcal{E} \to \text{Set}$, both $\pi_0$ and $\Delta$ preserve finite coproducts, so inducing an adjunction $\pi_0 \circ (-) \dashv \Delta \circ (-): \mathfrak{E}(\mathcal{C}, \text{Set}) \to \mathfrak{E}(\mathcal{C}, \mathcal{E})$, whose right adjoint must send the terminal object $\beta \in [\mathcal{C}, \text{Set}]$ to a terminal object $\Delta \beta \in \mathfrak{E}(\mathcal{C}, \mathcal{E})$. As $\mathcal{C}$ and $\mathcal{E}$ are extensive, it follows from this and Lemma 19 that $\mathfrak{E}(\mathcal{C}, \mathcal{E}) \cong [\mathcal{C}, \mathcal{E}]_{/\text{sc}} \Delta \beta$ where to the right we have the full subcategory of the slice category on the sum-cartesian transformations; recall that sum-cartesian means that the naturality squares at coproduct coprojections are pullbacks.

Using (5.1) we have, like before, an equivalence $[\mathcal{C}, \mathcal{E}]_{/\Delta \beta} \simeq [\text{el} \mathcal{E}, \mathcal{E}] \cong [\mathbb{U}_{\mathcal{E}}, \mathcal{E}]$; and, like before, an object $p: E \to \Delta \beta$ to the left is sum-cartesian just when the corresponding $\tilde{E} \in [\mathbb{U}_{\mathcal{E}}, \mathcal{E}]$ inverts the class $\mathcal{M}_\Sigma$ of continuous coproduct coprojections. Thus $\mathfrak{E}(\mathcal{C}, \mathcal{E}) \cong [\mathcal{C}, \mathcal{E}]_{/\text{sc}} \Delta \beta \simeq [\mathbb{U}_{\mathcal{E}}, \mathcal{E}]$ as desired.

It remains to show that the two directions of the equivalence are given as in (3.6) and (3.7). In the latter case this is clear from the construction using (5.1). In the other direction, if $A \in \mathfrak{E}(\mathcal{C}, \mathcal{E})$, then the corresponding $\tilde{A} \in [\mathbb{U}_{\mathcal{E}}, \mathcal{E}]$ has its value at $(X, \mathcal{U})$ given by the pullback to the left in:

$$
\begin{array}{ccc}
\tilde{A}(X, \mathcal{U}) & \longrightarrow & AX \\
\downarrow & & \downarrow \tau_X \\
\Delta \mathcal{U} & \longrightarrow & \Delta \beta X
\end{array}
$$

$$
\begin{array}{ccc}
AU & \xrightarrow{\Delta m} & AX \\
\uparrow \tau_U & & \downarrow \tau_X \\
\Delta \beta U & \xrightarrow{\Delta \beta m} & \Delta \beta X
\end{array}
$$

where $\tau: A \to \Delta \beta$ is induced by terminality of $\Delta \beta$ in $\mathfrak{E}(\mathcal{C}, \mathcal{E})$. Note, however, that $\mathcal{U}: 1 \to \beta X$ in $\text{Set}$ is the meet of the subobjects $(\beta U \to \beta X)_{U \in \mathcal{U}}$. Since $\Delta$ is a right adjoint, it preserves meets, as does pullback along $\tau_X$; consequently,
\[\hat{A}(X, \mathcal{U}) \text{ is the meet of the subobjects } (\tau_X^{-1}(\Delta \beta U) \to AX)_{U \in \mathcal{U}}. \text{ But since } \tau \text{ is sum-cartesian by Lemma } 19, \text{ the square right above is a pullback for any } m: U \to X \text{ in } \mathcal{U}, \text{ and so we conclude that } \hat{A} \text{ is given as in (3.6) by} \]
\[\hat{A}(X, \mathcal{U}) \cong \bigcap_{U \in \mathcal{U}} AU \subseteq AX.\]

5.2. Ultramatrices, ultraspans and the relation to indexed sums. We now wish to describe how this result recaptures the indexed sum of ultrafilters. In fact, we will do something slightly more general to draw as perfect an analogy as possible with Proposition 16. The first step there was to transport the strict monoidal structure on the category \(\mathfrak{F}(\mathcal{C}, \mathcal{C})\) to obtain a monoidal structure on the equivalent \([\mathcal{U}, \mathcal{C}]\). The analogue here is to transport the compositional structure of a 2-category of finite-coproduct-preserving functors along equivalences of each of its hom-categories to obtain an equivalent bicategory.

Definition 27. (i) The 2-category \(\mathfrak{F}_\mathcal{C}\) has sets \(X, Y, Z, \ldots\) as objects; hom-categories given by \(\mathfrak{F}_\mathcal{C}(X, Y) = \mathfrak{F}(\mathcal{C}X, \mathcal{C}Y)\); and composition given by the usual composition of functors and natural transformations.

(ii) The bicategory \(\mathcal{U}\mathcal{E}\mathcal{S}\mathcal{P}\) of ultrafilter species has sets as objects; hom-categories \(\mathcal{U}\mathcal{E}\mathcal{S}\mathcal{P}(X, Y) = [\mathcal{U}\mathcal{F}(\mathcal{C}X, \mathcal{C}Y)]\); and composition obtained from that of \(\mathfrak{F}_\mathcal{C}\) by transporting across the equivalences \(\mathcal{U}\mathcal{F}(\mathcal{C}X, \mathcal{C}Y) \cong [\mathcal{U}\mathcal{F}(\mathcal{C}X, \mathcal{C}Y)]\).

The nomenclature “ultrafilter species” echoes Joyal’s notion of a species of structures (\(\text{espéces de structures}\) [24]), and its generalisation in [15] to a bicategory \(\mathcal{E}\mathcal{S}\) of generalised species of structures. We will not labour the comparison, but suffice it to say that in both bicategories, composition is given by a substitution formula, which in the case of \(\mathcal{E}\mathcal{S}\) is given by equation (9) of \textit{ibid.}, and for \(\mathcal{U}\mathcal{E}\mathcal{S}\mathcal{P}\) is given by a suitable generalisation of (3.8).

In Proposition 16, we reconstructed the tensor product of ultrafilters by showing the representables in \([\mathcal{U}\mathcal{F}, \mathcal{C}]\) to be closed under the tensor product. To reconstruct the indexed sum of ultrafilters, we will similarly show that \textit{pointwise representable} 1-cells in \(\mathcal{U}\mathcal{E}\mathcal{S}\mathcal{P}\) are closed under composition. Here, \(F \in \mathcal{U}\mathcal{E}\mathcal{S}\mathcal{P}(X, Y) = [\mathcal{U}\mathcal{F}(\mathcal{C}X, \mathcal{C}Y)]\) is pointwise representable if each functor \(F(-)(y): \mathcal{F}_{\mathcal{C}X} \to \mathcal{C}\) is representable. The subcategory of pointwise representable functors is equivalent (via pointwise Yoneda) to the category \(\mathcal{F}(\mathcal{C}X, \mathcal{C}Y)\), and so a typical pointwise representable 1-cell is presented by a \(Y\)-indexed family of pairs \((M_y \in \mathcal{C}X, \mathcal{U}_y \in \beta(X, M_y))\). In fact, we prefer to think of these data in either one of the following two alternative ways.

Definition 28. Let \(X\) and \(Y\) be sets.

(i) An \textit{ultramatrix} from \(X\) to \(Y\) is a pair \((M, \mathcal{U})\) composed of a matrix of sets \(M \in \mathcal{C}X\times\mathcal{C}Y\) together with a \(Y\)-indexed family of ultrafilters \(\mathcal{U}_y\) on each column sum \(M_y := (\Sigma x \in X)M(x, y)\).

(ii) An \textit{ultrafamily} \((g, \mathcal{U})\): \(M \sim Y\) is a function \(g: M \to Y\) together with an ultrafilter \(\mathcal{U}_y\) on each fibre \(g^{-1}(y)\). An \textit{ultraspan} from \(X\) to \(Y\) is a span with
left leg a function and right leg an ultrafamily:

\[(5.2) \begin{array}{c} M \\ f \end{array} \rightarrow \begin{array}{c} X \\ \downarrow (g,\mathcal{U}) \end{array} \rightarrow \begin{array}{c} Y. \\ \downarrow \end{array} \]

It is easy to see using (2.1) that both ultramatrices and ultraspans from \(X\) to \(Y\) correspond to pointwise representables in \(\mathcal{U}Esp(X, Y)\), and so to certain finite-coproduct-preserving functors \(\text{Set}^X \rightarrow \text{Set}^Y\). As in the introduction, we may call these \textit{generalised ultraproduct functors}. Using Proposition 24, we see that, one the on hand, the generalised ultraproduct functor \(\text{Set}^X \rightarrow \text{Set}^Y\) encoded by the ultramatrix \((M, \mathcal{U})\) is given by:

\[(5.3) \quad \left( H(x) \mid x \in X \right) \mapsto \left( (\Pi_{(g,\mathcal{U})}(x, m) \in M_y)H(x) \mid y \in Y \right). \]

On the other hand, the ultraspans \((f, (g, \mathcal{U})): X \rightarrow Y\) encodes the functor

\[\text{Set}^X \xrightarrow{\text{Set}^f} \text{Set}^M \xrightarrow{\Pi_{(g,\mathcal{U})}} \text{Set}^Y\]

where \(\Pi_{(g,\mathcal{U})}\) is given by “ultraproduct on each fibre”; i.e., its \(y\)-component is given by restriction \(\text{Set}^M \rightarrow \text{Set}^{g^{-1}y}\) followed by ultraproduct \(\Pi_{(g,\mathcal{U})}: \text{Set}^{g^{-1}y} \rightarrow \text{Set}^Y\).

The next two definitions are intended to describe how pointwise representable 1-cells in \(\mathcal{U}Esp\) compose in terms of the representing ultramatrices or ultraspans.

**Definition 29.** If \((M, \mathcal{U})\) and \((N, \mathcal{V})\) are ultramatrices from \(X\) to \(Y\) and from \(Y\) to \(Z\), then their \textit{composition} is the ultramatrix \((N \cdot M, \mathcal{V} \cdot \mathcal{U})\) from \(X\) to \(Z\) whose first component is given by the usual matrix multiplication:

\[(N \cdot M)(x, z) = (\Sigma y \in Y)(N(y, z) \times M(x, y)).\]

As for the second component, note that for each \(z \in Z\) we have an isomorphism

\[(5.4) \quad (\Sigma (y, n) \in N_z)M_y \cong (N \cdot M)_z\]

sending \((y, n, x, m)\) to \((x, y, n, m)\). We can therefore define the ultrafilter \((\mathcal{V} \cdot \mathcal{U})_z\) on \((N \cdot M)_z\) to be the transport across (5.4) of the ultrafilter on \((\Sigma (y, n) \in N_z)M_y\) given by the indexed sum \((\Sigma_{\mathcal{V}, n \in k^{-1}z})\mathcal{U}_y\).

**Definition 30.** Given ultraspans \((f, (g, \mathcal{U})): X \rightarrow Y\) and \((h, (k, \mathcal{V})): Y \rightarrow Z\), their \textit{composition} is the ultraspans whose legs are given by the outer composites in:

\[\begin{array}{c} M \times Y N \\ \downarrow p \leftrightarrow \begin{array}{c} M \\ f \end{array} \rightarrow \begin{array}{c} X \\ \downarrow (g,\mathcal{U}) \end{array} \rightarrow \begin{array}{c} Y \\ \downarrow h \end{array} \rightarrow \begin{array}{c} N \\ \downarrow (k,\mathcal{V}) \end{array} \rightarrow \begin{array}{c} Z. \\ \downarrow \end{array} \]

Here, \(p\) and \(q\) constitute a pullback of \(g\) and \(h\) in \(\text{Set}\). To the top right, the pullback ultrafamily \((q, \mathcal{W})\): \(M \times Y N \rightarrow N\) has \(\mathcal{W}_n\) given by the transport of \(\mathcal{U}_{hn}\) across the isomorphism \(g^{-1}(hn) \cong q^{-1}(n)\). Finally, the composite \((kq, \mathcal{V}W)\) of the ultrafamilies \((q, \mathcal{W})\) and \((k, \mathcal{V})\) has \((\mathcal{V}W)_z\) given by the transport of \((\Sigma_{\mathcal{V}, n \in k^{-1}z})\mathcal{W}_n\) across the isomorphism \((\Sigma n \in k^{-1}z)q^{-1}n \cong (kq)^{-1}z)\).
The validity of these descriptions is confirmed by:

**Proposition 31.** The pointwise representable 1-cells in \( \mathfrak{UEsp} \) are closed under composition, with the induced composition on ultramatrices and ultraspans given as in Definition 29 and Definition 30 respectively.

**Proof.** The identity 1-cells in \( \mathfrak{UEsp} \) are easily seen to be pointwise representable. As for binary composition, the composition laws in Definitions 29 and 30 correspond under (2.1), so that it suffices to check the claim on ultramatrices. So let \( F \in \mathfrak{UEsp}(X,Y) \) and \( G \in \mathfrak{UEsp}(Y,Z) \) be represented by the respective ultramatrices \( (M, U) \) and \( (N, V) \). By (5.3), the corresponding generalised ultraproduct functors \( \int F \in \mathcal{F}(\text{Set}^X, \text{Set}^Y) \) and \( \int G \in \mathcal{F}(\text{Set}^Y, \text{Set}^Z) \) have respective actions on objects

\[
(\int F)V(y) = (\Pi_{x \in X} U(x, m))H(x) \quad \text{and} \quad (\int G)N(z) = (\Pi_{y \in Y} V(y, n))K(y) .
\]

Therefore \( \int GF \cong \int G \circ \int F : \text{Set}^X \to \text{Set}^Z \) satisfies

\[
(\int GF)N(z) \cong (\Pi_{y \in Y} V(y, n))M(y)H(x) \cong (\Pi_{y \in Y} \{ y \in Y \mid (y, n) \in N \})M(y)H(x) \cong (\Pi_{y \in Y} \{ y \in Y \mid (y, n) \in N \} \cdot M)H(x) ,
\]

using Proposition 9 and the definition of \( (V \cdot U)z \). Thus, by (5.3) again, the pointwise representability of \( GF \) is witnessed by the ultramatrices \( (N \cdot M, V \cdot U) \).

It follows from this result that there are bicategories \( \mathfrak{Utx} \) (resp., \( \mathfrak{Us} \)) in which objects are sets; 1-cells are ultramatrices (resp., ultraspans) composing as in Definition 29 (resp., Definition 30); and 2-cells are determined by the requirement that each bicategory be biequivalent to the locally full sub-bicategory of \( \mathfrak{UEsp} \) on the pointwise representable 1-cells.

It remains to show that the composition laws in \( \mathfrak{Utx} \) and \( \mathfrak{Us} \) allow us to reconstruct the indexed sum of ultrafilters, so fulfilling the objective of this section. This is easiest to see in the case of \( \mathfrak{Us} \). Suppose that we are given a set \( X \) equipped with an ultrafilter \( U \) and an \( X \)-indexed family of sets \( Y(x) \) each equipped with an ultrafilter \( V(x) \). We can represent these data as a pair of composable ultraspans as to the left in:

\[
\begin{align*}
\xymatrix{ & Y \ar[dl]_1 \ar[dr] & X \ar[dl]_1 \ar[dr] & Y \ar[dl]_1 \ar[dr] & \ar[dl]_1 \\
X & X & X & X & X \ar[dl]_1 \ar[dr]_1 \ar[dl]_1 \ar[dr]_1 \ar[dl]_1 }
\end{align*}
\]

whose composite encodes the indexed sum \( U \cdot V \) as right above.

**5.3. Relation to ultracategories.** In Remark 17 above, we drew the correspondence between \( [\mathfrak{Uf}, \text{Set}] \)-enriched categories admitting copowers by representables, and ordinary categories endowed with abstract ultrapower functors. We are now in a position to extend this so as to capture categories endowed with abstract ultraproduct functors. Where before we used categories enriched in a monoidal category, we now require categories enriched in a bicategory as in [41].
If \( \mathcal{W} \) is a bicategory, then a \( \mathcal{W} \)-enriched category \( \mathcal{C} \) involves a set of objects \( A, B, C, \ldots \); for each object \( A \) an extent \( \epsilon_A \in \mathcal{W} \); for each pair of objects \( A, B \) a hom-object \( \mathcal{C}(A, B) \in \mathcal{W}(\epsilon_A, \epsilon_B) \); and composition and identity maps like before. In this setting we can speak of the copower of \( A \in \mathcal{C} \) by a 1-cell \( W \in \mathcal{W}(\epsilon_A, Y) \); this is an object \( W \cdot A \) of extent \( Y \) satisfying a suitable universal property.

Comparing Proposition 16 and Proposition 31 suggests how the above notions should be applied: rather than \( [\mathcal{U}, \text{Set}] \)-enriched categories with copowers by representables, we consider \( \mathbb{U}\text{Esp} \)-enriched categories with copowers by pointwise representable 1-cells. We might guess that such enriched categories correspond to ordinary categories \( \mathcal{C} \) admitting abstract ultraproduct functors \( \Pi_U : \mathcal{C}^X \to \mathcal{C} \).

Under this correspondence, \( \mathcal{C} \) would correspond to the \( \mathbb{U}\text{Esp} \)-category \( \mathcal{C} \) whose objects of extent \( X \) are \( X \)-indexed families of objects of \( \mathcal{C} \), and whose hom-object \( \mathcal{C}(A, B) : \mathbb{U}\text{Set}^X \to \text{Set}^Y \) is given at \( (f : C \to X, U \in \beta(X.C)) \) in \( \mathbb{U}\text{Set}^X \) by

\[
\mathcal{C}(A, B)(f, U)(y) = \mathcal{C}(\Pi_U(x, c) \in X.C)A(x), B(y)) .
\]

The reality is slightly more subtle; while some details still require sorting out, it appears that the \( \mathbb{U}\text{Esp} \)-enriched categories with copowers as above correspond to \( \text{Set} \)-indexed prestacks—i.e., pseudo-functors \( \mathbb{C} : \text{Set}^{\text{op}} \to \text{CAT} \) satisfying a descent condition—equipped with suitably coherent abstract ultrapower functors \( \Pi_{(f, U)} : \mathbb{C}_X \to \mathbb{C}_Y \) for each ultrafamily \( (f, U) : X \rightrightarrows Y \). The proof uses the identification of the pointwise representable 1-cells in \( \mathbb{U}\text{Esp} \) as ultraspans, together with [20, Theorem 3.2], which identifies \( \mathcal{W} \)-enriched categories admitting copowers by 1-cells in \( \omega \subset \mathcal{W} \) with certain homomorphisms of bicategories \( \omega \to \text{CAT} \).

While the details must await a further paper, these observations draw an interesting link to Makkai’s ultracategories [36]. As in the introduction, an ultracategory is a category endowed with abstract ultraproduct structure along with interpretations for any ultramorphism, i.e., “definable map between ultraproducts”. Makkai’s main result in [36] is that the ultracategory structure on the category of models of a coherent theory \( T \) in intuitionistic first-order logic is sufficient to reconstruct \( T \) to within Morita equivalence; more precisely, it suffices to reconstruct the classifying pretopos of \( T \). (A corresponding reconstruction result for classical first-order theories was given in [37].)

One of the least intuitive aspects of [36] is the subtle definition of an ultramorphism. The point is that something more than abstract ultraproduct functors alone is necessary to prove the reconstruction theorem. In [32], Lurie makes an alternative suggestion for what this additional structure should be; and although we have not yet completed the analysis, it seems that this additional structure is exactly what \( \mathbb{U}\text{Esp} \)-enrichment provides besides the existence of abstract ultraproduct functors. In future work we hope to investigate this further with a view to giving a purely enriched-categorical proof of Makkai’s reconstruction result.

6. Locally connected classifying toposes

In Section 4.3, we discussed the classifying Boolean pretopos of a first-order theory: the universal Boolean pretopos containing a model of the theory. In a similar vein, one can speak about classifying toposes of various kinds of structure,
so long as the structure in question is interpretable in any Grothendieck topos, and preserved by the structure-preserving maps of toposes. There is a well-developed theory of classifying toposes, in which it is possible to give explicit descriptions of the classifying toposes in question. There is also a corresponding theory of *locally connected classifying toposes*; and while in this case, there are existence results due to Funk [17], rather few explicit constructions are known. The goal in this section is to exploit our preceding theorems to produce concrete descriptions of locally connected classifying toposes in some particular cases.

6.1. **The lextensive case.** In this section, as a warm-up to our main result, we construct the locally connected classifying topos of a small lextensive category—that is, a category which is both finitely complete and extensive.

We first make precise what we mean by this. Recall that a geometric morphism \( f : \mathcal{E} \to \mathcal{F} \) between toposes is an adjoint pair of functors \( f^* \dashv f_* : \mathcal{E} \to \mathcal{F} \) such that \( f^* \) (the inverse image functor) preserves finite limits. We write \( \text{LCGTop} \) for the 2-category of locally connected Grothendieck toposes, geometric morphisms and natural transformations \( f^* \Rightarrow g^* \), and write \( \text{Lext} \) for the corresponding 2-category of lextensive categories, lextensive functors (i.e., ones preserving finite limits and finite coproducts) and arbitrary natural transformations. As every locally connected Grothendieck topos and every inverse image functor between such is lextensive, we have a forgetful 2-functor \( \text{LCGTop}^{\text{op}} \to \text{Lext} \).

**Definition 32.** A locally connected classifying topos for an extensive category \( \mathcal{C} \) is a left biadjoint at \( \mathcal{C} \) for the forgetful 2-functor \( \text{LCGTop}^{\text{op}} \to \text{Lext} \).

Here, and in what follows, when we speak of a left biadjoint at \( \mathcal{X} \) for a 2-functor \( U : \mathcal{A} \to \mathcal{B} \), we mean a birepresentation (in the sense of [40]) for the 2-functor \( \mathcal{B}(\mathcal{X}, U-) : \mathcal{A} \to \mathcal{CAT} \). More concretely, then, a locally connected classifying topos for the lextensive \( \mathcal{C} \) comprises a locally connected Grothendieck topos \( \mathcal{Lc}(\mathcal{C}) \) and a lextensive functor \( \eta : \mathcal{C} \to \mathcal{Lc}(\mathcal{C}) \) which is universal in the sense that, for each locally connected Grothendieck topos \( \mathcal{E} \), we have an equivalence:

\[
\text{LCGTop}(\mathcal{E}, \mathcal{Lc}(\mathcal{C})) \simeq \text{Lext}(\mathcal{C}, \mathcal{E})
\]

induced by the assignation \( f \mapsto f^* \circ \eta \).

Our goal is to give an explicit construction of a locally connected classifying topos for any small lextensive category \( \mathcal{C} \). For this, we require the result sometimes known as *Diaconescu’s theorem*; it can be found proved in, for example, [33, Theorem VII.7.2].

**Proposition 33.** If \( \mathcal{A} \) is a small category, then the presheaf topos \( \mathcal{A}^{\text{op}}, \text{Set} \) classifies flat functors out of \( \mathcal{A} \). More precisely, for each Grothendieck topos \( \mathcal{E} \), the assignation \( f \mapsto f^* \circ y \) induces an equivalence of categories

\[
\text{GTop}(\mathcal{E}, \mathcal{A}^{\text{op}}, \text{Set}) \simeq \mathcal{F}\text{lat}(\mathcal{A}, \mathcal{E})
\]

Here, we define \( \mathcal{F}\text{lat}(\mathcal{A}, \mathcal{E}) \) as the full subcategory of \( \mathcal{A}, \mathcal{E} \) on the flat functors, but for this we should clarify what “flat” means. One definition is that \( F : \mathcal{A} \to \mathcal{E} \) is flat just when \( \text{Lan}_y F : \mathcal{A}^{\text{op}}, \text{Set} \to \mathcal{E} \), its left Kan extension along the Yoneda embedding of \( \mathcal{A}^{\text{op}}, \text{Set} \), preserves finite limits; this is a general categorical definition which makes sense for any small \( \mathcal{A} \) and cocomplete \( \mathcal{E} \). On the other
hand, when $\mathcal{E}$ is a Grothendieck topos as above, a more explicit characterisation is possible which generalises a well-known characterisation when $\mathcal{E} = \mathcal{S}et$. 

Given $F \in [\mathcal{A}, \mathcal{E}]$, we write $\text{el} F$ for the category of elements of $F$: the internal category in $\mathcal{E}$ with underlying graph

$$\sum_{a, b \in \mathcal{A}} \sum_{f \in \mathcal{A}(a, b)} Da \xrightarrow{s} \sum_{a \in \mathcal{A}} Da$$

where $s$ maps the $(a, b, f)$-summand to the $a$-summand via $1_{Da}$, and where $t$ maps the $(a, b, f)$-summand to the $b$-summand via $Df$. There is a standard notion—see, for example [22, Definition B2.6.2]—of what it means for an internal category $\mathcal{C}$ in a topos to be cofiltered; in the internal language of the topos, it says that “every finite diagram in $\mathcal{C}$ has a cocone under it”. The key result we will need is the following; for a proof, see [22, Theorem B3.2.7].

**Proposition 34.** If $\mathcal{A}$ is a small category and $\mathcal{E}$ is a Grothendieck topos, then $F: \mathcal{A} \to \mathcal{E}$ is flat if and only if the internal category $\text{el} F$ in $\mathcal{E}$ is cofiltered.

With these preliminaries in place, we can now give:

**Proposition 35.** If $\mathcal{C}$ is small and lextensive, then $[[\mathcal{F} \mathcal{C}^{\text{op}}, \mathcal{S}et]]$ is a locally connected classifying topos for $\mathcal{C}$.

**Proof.** Like any presheaf topos, $[[\mathcal{F} \mathcal{C}^{\text{op}}, \mathcal{S}et]]$ is locally connected. For the classifying property, we must exhibit equivalences $\mathcal{L}\mathcal{C}\mathcal{O}\mathcal{T}\mathcal{op}(\mathcal{E}, [[\mathcal{F} \mathcal{C}^{\text{op}}, \mathcal{S}et]]) \simeq \mathcal{L}et(\mathcal{C}, \mathcal{E})$, pseudonaturally in $\mathcal{E}$, which we will do by composing pseudonatural equivalences:

$$(6.3) \quad \mathcal{L}\mathcal{C}\mathcal{O}\mathcal{T}\mathcal{op}(\mathcal{E}, [[\mathcal{F} \mathcal{C}^{\text{op}}, \mathcal{S}et]]) \xrightarrow{\sim} \mathcal{F}\text{lat}(\mathcal{F} \mathcal{C}, \mathcal{E}) \xrightarrow{\sim} \mathcal{L}et(\mathcal{C}, \mathcal{E}) .$$

The first of these is (6.2). As for the second, we have by Theorem 26 that

$$(6.4) \quad [[\mathcal{F} \mathcal{C}, \mathcal{E}]] \simeq \mathcal{F}\mathcal{C}(\mathcal{C}, \mathcal{E})$$

for any locally connected Grothendieck topos $\mathcal{E}$, and by considering the explicit formula (3.7) for the rightward direction, we see that these equivalences are pseudonatural in inverse image functors. We will thus have the desired pseudonatural equivalence if we can show that, in (6.4), the flat functors on the left-hand side correspond to the finite-limit-preserving ones on the right.

Towards this goal, we recall from Definition 21 the category $\mathcal{U} \mathcal{C} \mathcal{E}$ of which $\mathcal{U} \mathcal{F} \mathcal{C}$ is a localisation, and consider the span $\pi: \mathcal{C} \leftarrow \mathcal{U} \mathcal{C} \mathcal{E} \rightarrow \mathcal{U} \mathcal{F} \mathcal{C}$ whose two legs are the forgetful functor and the localisation functor respectively. It is easy to see from the formula (3.7) that the left-to-right direction of (6.4) sends $B: \mathcal{F} \mathcal{C} \to \mathcal{E}$ to its image under the composite functor

$$[[\mathcal{U} \mathcal{F} \mathcal{C}, \mathcal{E}]] \xrightarrow{\mathcal{L}an_{\pi}} [[\mathcal{U} \mathcal{C} \mathcal{E}, \mathcal{E}]] \xrightarrow{\mathcal{L}an_{\pi}} [[\mathcal{C}, \mathcal{E}]].$$

It therefore suffices to prove that:

(i) $B: \mathcal{U} \mathcal{F} \mathcal{C} \to \mathcal{E}$ is flat if and only if $B \pi: \mathcal{U} \mathcal{C} \mathcal{E} \to \mathcal{E}$ is flat. We saw above that $\mathcal{U} \mathcal{F} \mathcal{C} \cong \mathcal{U} \mathcal{C} \mathcal{E}[M^{-1}_{\Sigma}]$, the localisation at the class of continuous coproduct coprojections. Since $M_{\Sigma}$ is a pullback-stable, composition-closed class of monomorphisms, there is a Grothendieck topology $J$ on $\mathcal{U} \mathcal{C} \mathcal{E}$ whose covering sieves are those which contain any map in $M_{\Sigma}$. The $J$-sheaves are thus the functors $F: \mathcal{U} \mathcal{C} \mathcal{E}^{\text{op}} \to \mathcal{S}et$ which invert each $m \in M_{\Sigma}$, and so we may identify
ULTRAFILTERS AND LOCALLY CONNECTED CLASSIFYING TOPOSES 23

\[ UF_{\text{op}}, \text{Set} \text{ with } Sh(UE_{\text{op}}), \text{ and the sheafification adjunction with the adjunction } \text{Lan}_\gamma \circ \iota^* : [UF_{\text{op}}, \text{Set}] \to [UE_{\text{op}}, \text{Set}]; \text{ so in particular, Lan}_\gamma \text{ preserves finite limits. We now use this to prove the claim. Note that } \text{Lan}_\gamma(B_\iota) \cong \text{Lan}_\gamma(B) \circ \text{Lan}_\gamma, \text{ so that if } B \text{ is flat, then so too is } B_\iota. \text{ On the other hand, since } \text{Lan}_\gamma \circ \iota^* \cong 1, \text{ we have that } \text{Lan}_\gamma(B_\iota) \cong \text{Lan}_\gamma(B) \circ \iota^* \text{ so that if } B_\iota \text{ is flat then so too is } B.

(ii) \( F : UE_{\text{op}} \to E \text{ is flat if and only if } \text{Lan}_\pi F : C \to E \text{ preserves finite limits.} \)

Since the value of \( \text{Lan}_\pi F : C \to E \) at \( X \) is \( \sum_{U \in \beta X} F(X, U) \), it is an easy calculation to see that the internal categories \( \text{el}(F) \) and \( \text{el}(\text{Lan}_\pi F) \) are isomorphic. So \( F \) is flat if and only if \( \text{Lan}_\pi F \) is flat. But since \( C \) admits all finite limits, \( \text{Lan}_\pi F \) is flat if and only if it is finite-limit-preserving; see, for example [22, Lemma B3.2.5]. □

By tracing the identity geometric morphism on \([UF_{\text{op}}, \text{Set}]\) through this proof, we see that the universal lextensive functor \( \eta : C \to [UF_{\text{op}}, \text{Set}] \) is the image under (3.7) of the Yoneda embedding \( UF_{\text{op}} \to [UF_{\text{op}}, \text{Set}] \), and so given by:

\[ \eta(X) = \sum_{U \in \beta X} y(X, U). \]

6.2. The pretopos case. Let us now write \( \mathcal{P} \text{retop} \) for the 2-category of pretoposes, pretopos morphisms and all natural transformations. Like before, every locally connected Grothendieck topos is a pretopos and every inverse image functor is a pretopos morphism, so that we have a forgetful 2-functor \( \text{LCGTop}_{\text{op}} \to \mathcal{P} \text{retop} \).

**Definition 36.** A locally connected classifying topos for a pretopos \( C \) is a left biadjoint at \( C \) for the forgetful 2-functor \( \text{LCGTop}_{\text{op}} \to \mathcal{P} \text{retop} \).

It is known that every small pretopos \( C \) has a locally connected classifying topos. To see this, we factor the forgetful 2-functor \( \text{LCGTop}_{\text{op}} \to \mathcal{P} \text{retop} \) as

\[ \text{LCGTop}_{\text{op}} \to \text{GTop}_{\text{op}} \to \mathcal{P} \text{retop}. \]

The second factor is well-known to have a left biadjoint at every small pretopos \( C \), given by the topos of sheaves \( \text{Sh}(C) \) for the topology of finite jointly epimorphic families. On the other hand, the first factor is known to have a left biadjoint given by the locally connected coclosure of [17]. It follows that the composite has a left biadjoint at every small pretopos.

One difficulty with the preceding argument is that the construction of the locally connected coclosure in [17] is inexplicit, relying at a crucial point on the adjoint functor theorem. Our objective in this section is to give a concrete description of the locally connected classifying topos of any small De Morgan pretopos.

The notion of De Morgan pretopos is an obvious generalisation of the notion of De Morgan topos described, for example in [23, §D4.6]. In giving the definition, we recall a pseudocomplement of an element \( a \) in a distributive lattice is an element \( \neg a \) which is disjoint from \( a \), and is moreover the maximal such element; i.e., such that \( a \land b = \bot \) if and only if \( b \leq \neg a \).

**Definition 37.** A distributive lattice \( A \) is a Stone algebra [21] if it admits all pseudocomplements and satisfies \( \neg a \lor \neg \neg a = \top \) for all \( a \in A \). A pretopos \( C \) is De Morgan if each subobject lattice \( \text{Sub}(C)(X) \) is a Stone algebra.
An equivalent characterisation of a De Morgan pretopos is as one in which each inclusion of meet semi-lattices \( \text{Sum}_E(X) \rightarrow \text{Sub}_C(X) \) has a left adjoint sending \( A \) to \( \neg \neg A \). The relevance of the condition to our investigations is isolated in the following result, whose significance will become clear shortly. In its proof, we use the operation \( \exists_f : \text{Sub}_C(X) \rightarrow \text{Sub}_C(Y) \) of direct image along a map \( f : X \rightarrow Y \) of a pretopos \( C \). This operation is left adjoint to pullback \( f^{-1} : \text{Sub}_C(Y) \rightarrow \text{Sub}_C(X) \) and satisfies the Beck–Chevalley and Frobenius conditions; see [22, \$A1.3].

**Proposition 38.** If \( C \) is a De Morgan pretopos, then \( \mathcal{UF}_C \) satisfies the right Ore condition: that is, each cospan in \( \mathcal{UF}_C \) as in the solid part of the following diagram can be completed to a commuting square as shown:

\[
\begin{array}{ccc}
(Z, W) & \xrightarrow{[g_2]} & (X_2, U_2) \\
\downarrow & & \downarrow [f_2] \\
(X_1, U_1) & \xrightarrow{[f_1]} & (Y, V)
\end{array}
\]

(6.5)

**Proof.** Since every map in \( \mathcal{UF}_C \) factors as an isomorphism followed by the equivalence class of a total map, we lose no generality in assuming that the \( f_i \)'s in (6.5) are total. We can therefore form their pullback \( g_1 : X_1 \leftarrow Z \rightarrow X_2 ; g_2 \) in \( C \), and consider the subset \( \mathcal{F} \subseteq \text{Sum}_C(Z) \) given as the upward closure of

\[
\{ g_1^{-1}(U_1) \cap g_2^{-1}(U_2) : U_1 \in \mathcal{U}_1, U_2 \in \mathcal{U}_2 \}.
\]

(6.6)

This subset is easily a filter on \( \text{Sum}_C(Z) \), and we claim it is a proper filter; thus, for any \( U_1 \in \mathcal{U}_1 \) and \( U_2 \in \mathcal{U}_2 \) we must show that \( g_1^{-1}(U_1) \cap g_2^{-1}(U_2) \neq \perp \). Now, by Frobenius, Beck–Chevalley, and Frobenius we have

\[
\exists f_1 g_1 (g_1^{-1}(U_1) \cap g_2^{-1}(U_2)) = \exists f_1 (U_1 \cap \exists g_1 (g_2^{-1}(U_2))) \\
= \exists f_1 (U_1 \cap f_1^{-1}(\exists f_2 (U_2))) \\
= \exists f_1 (f_1(U_1) \cap \exists f_2 (U_2)),
\]

and so, since direct image preserves and reflects \( \perp \), we must equally show that \( \exists f_1(U_1) \cap \exists f_2 (U_2) \neq \perp \). If we set \( V_i = \neg \neg \exists f_i (U_i) \) then, by standard properties of pseudocomplementation, this is in turn equivalent to showing that \( V_1 \cap V_2 \neq \perp \). Since \( C \) is De Morgan, we have \( V_i \in \text{Sum}_C(Y) \); moreover, \( U_i \in \mathcal{U}_i \) and \( U_i \subseteq f_i^{-1}(\exists f_i (U_i)) \subseteq f_i^{-1}(V_i) \) implies \( f_i^{-1}(V_i) \in \mathcal{U}_i \), and so \( V_i \in \mathcal{V} \) since \( (f_i)_!(U_i) = V \). Since \( \mathcal{V} \) is an ultrafilter, we conclude that \( V_1 \cap V_2 \neq \perp \) as desired.

This proves that (6.6) generates a proper filter \( \mathcal{F} \). By the Boolean prime ideal theorem, we can extend this to an ultrafilter \( \mathcal{W} \in \beta Z \), which by construction satisfies \( \mathcal{U}_i \subseteq (g_i)_!(\mathcal{W}) \) for \( i = 1, 2 \), and so \( \mathcal{U}_i = (g_i)_!(\mathcal{W}) \) (since both sides are ultrafilters). We have thus completed (6.6) to a commuting square as desired. \( \square \)

The key to constructing the locally connected classifying topos of a small De Morgan pretopos is the following standard result on geometric morphisms into sheaf toposes proved, for example, in [33, Lemma VII.7.3]. In the statement, we write \( \text{CondFlat}(A, \mathcal{E}) \) for the category of flat functors \( A \rightarrow \mathcal{E} \) which are also cover-preserving, in the sense of sending covers to jointly epimorphic families.
Proposition 39. Let \( A \) be a small site and \( i : \text{Sh}(A) \to [A^{\text{op}}, \text{Set}] \) the associated inclusion of toposes. Under the equivalence (6.2), a geometric morphism to the left factors through \( i \) just when the corresponding flat functor to the right is cover-preserving. Consequently, (6.2) restricts back to an equivalence

\begin{equation}
\mathcal{G}\text{Top}(\mathcal{E}, \text{Sh}(A)) \simeq \text{CovFlat}(A, \mathcal{E}).
\end{equation}

The locally connected classifying topos of the small De Morgan pretopos \( \mathcal{C} \) will be obtained as a topos of sheaves on \( \mathcal{U}\mathcal{F}_C \) for a suitable Grothendieck topology, and its universal property verified via a chain of pseudonatural equivalences

\( \mathcal{L}\mathcal{G}\text{Top}(\mathcal{E}, \text{Sh}(\mathcal{U}\mathcal{F}_C)) \simeq \text{CovFlat}(\mathcal{U}\mathcal{F}_C, \mathcal{E}) \simeq \mathcal{P}\text{retop}(\mathcal{C}, \mathcal{E}) \), each of whose terms is a restriction of the corresponding term in (6.3).

Since a pretopos morphism out of \( \mathcal{C} \) is a lextensive functor which also preserves regular epimorphisms, the topology on \( \mathcal{U}\mathcal{F}_C \) must be chosen so that, under the equivalence \( \mathcal{F}\text{lat}(\mathcal{U}\mathcal{F}_C, \mathcal{E}) \simeq \text{Lext}(\mathcal{C}, \mathcal{E}) \) of (6.3), the cover-preserving functors to the left correspond to the regular-epimorphism-preserving ones to the right.

We now describe such a topology, specifying it in terms of a coverage [23, Definition C2.1.1]; this involves assigning to each object \( X \) a set of covering families \( (f_i : X_i \to X \mid i \in I) \) satisfying the stability property:

(C) For any cover \( (f_i : X_i \to X \mid i \in I) \) and any map \( g : Y \to X \) in \( A \), there is a cover \( (h_j : Y_j \to Y \mid j \in J) \) such that each \( gh_j \) factors through some \( f_i \).

Proposition 40. Let \( \mathcal{C} \) be a pretopos. There is a coverage on \( \mathcal{U}\mathcal{F}_C \) for which a typical cover of the object \( (Y, \mathcal{V}) \in \mathcal{U}\mathcal{F}_C \) is of the form

\begin{equation}
(f, \mathcal{V}) := ([f] : (X, \mathcal{U}) \to (Y, \mathcal{V}) \mid \mathcal{U} \in \beta X, f(\mathcal{U}) = \mathcal{V})
\end{equation}

for any \( f : X \to Y \) whose image \( \text{im } f \to Y \) is (a coproduct injection and) in \( \mathcal{V} \).

Proof. We must verify condition (C). So consider \( (f, \mathcal{V}) \) as above and a map \( [g] : (Y', \mathcal{V}') \to (Y, \mathcal{V}) \) in \( \mathcal{U}\mathcal{F}_C \) defined on some \( m : V' \to Y' \) in \( \mathcal{V}' \). We first pull back \( f \) along \( g \) in \( \mathcal{C} \) as left below, and now define \( f' = mq : X' \to Y' \). By assumption, \( \text{im } f \in \mathcal{V} \); since \( g \) is continuous and image factorisations are pullback-stable, it follows that \( \text{im } f' \in \mathcal{V}' \). Moreover, for each \( [f'] : (X', \mathcal{U}') \to (Y', \mathcal{V}') \) in \( \langle f', \mathcal{V}' \rangle \), the composite \( [gf'] \) factorises through a map in \( (f, \mathcal{V}) \) as to the right in:

\[
\begin{array}{ccc}
X' & \xrightarrow{p} & X \\
q \downarrow & & \downarrow f \\
V' & \xrightarrow{g} & Y \\
\end{array}
\quad
\begin{array}{ccc}
(X', \mathcal{U}') & \xrightarrow{[f]} & (X, \mathcal{U}) \\
[|f|] \downarrow & & \downarrow [|f|] \\
(Y', \mathcal{V}') & \xrightarrow{[g]} & (Y, \mathcal{V}) \\
\end{array}
\]

This proves that the covers do indeed satisfy condition (C). \( \square \)

We write \( \text{Sh}(\mathcal{U}\mathcal{F}_C) \) for the topos of sheaves on \( \mathcal{U}\mathcal{F}_C \) for this coverage.

Theorem 41. Let \( \mathcal{C} \) be a small De Morgan pretopos. The topos \( \text{Sh}(\mathcal{U}\mathcal{F}_C) \) is a locally connected classifying topos for \( \mathcal{C} \), and is itself De Morgan.

Proof. We begin by showing that \( \text{Sh}(\mathcal{U}\mathcal{F}_C) \) is locally connected and De Morgan. Since \( \mathcal{C} \) is De Morgan, we know by Proposition 38 that \( \mathcal{U}\mathcal{F}_C \) satisfies the right Ore condition, and so by [23, Examples C3.3.11(a)] and [11, Corollary 2.8], the
sheaf topos \( \text{Sh}(\mathcal{F}_\mathcal{E}) \) will be both locally connected and De Morgan so long as every covering family \( \langle f, \mathcal{V} \rangle \) as in (6.8) is non-empty. Thus, given \( \mathcal{V} \in \beta \mathcal{Y} \) and \( f: X \to Y \) in \( \mathcal{E} \) with \( \text{im } f \in \mathcal{V} \), we must show that there exists an ultrafilter \( \mathcal{U} \in \beta X \) with \( f_!(\mathcal{U}) = \mathcal{V} \). Much as in Proposition 38, we consider the subset \( \mathcal{F} \subseteq \text{Sum}_\mathcal{E}(X) \) given as the upwards-closure of
\[
\{ f^{-1}(V) : V \in \mathcal{V} \}.
\]
Like there, \( \mathcal{F} \) is a filter which we claim is moreover proper. Indeed, if \( \perp = f^{-1}(V) \) for some \( V \in \text{Sum}_\mathcal{E}(Y) \), then also \( \perp = \exists f(f^{-1}(V) \cap T) = V \cap \text{im } f \) by Frobenius; whence \( V \notin \mathcal{V} \) since \( \text{im } f \notin \mathcal{V} \). Like before, we can now use the Boolean prime ideal theorem to find an ultrafilter \( \mathcal{U} \subseteq \text{Sum}_\mathcal{E}(X) \) extending \( \mathcal{F} \) which, by construction, will satisfy \( \mathcal{V} \subseteq f_!(\mathcal{U}) \) and hence (since both are ultrafilters) \( \mathcal{V} = f_!(\mathcal{U}) \).

So \( \text{Sh}(\mathcal{F}_\mathcal{E}) \) is locally connected and De Morgan; it remains to verify the classifying property, for which we must exhibit equivalences \( \text{LCSet}(\mathcal{E}, \text{Sh}(\mathcal{F}_\mathcal{E})), \text{Set}) \simeq \text{Pretop}(\mathcal{E}, \mathcal{E}) \), pseudonaturally in \( \mathcal{E} \). As discussed above, these will be obtained by composing pseudonatural equivalences:
\[
\text{LCSet}(\mathcal{E}, \text{Sh}(\mathcal{F}_\mathcal{E})) \xrightarrow{\simeq} \text{CovFlat}(\mathcal{F}_\mathcal{E}, \mathcal{E}) \xrightarrow{\simeq} \text{Pretop}(\mathcal{E}, \mathcal{E})
\]
of which the first is (6.7), and the second is obtained by restricting the right-hand equivalence \( \text{Flat}(\mathcal{F}_\mathcal{E}, \mathcal{E}) \simeq \text{Lex}(\mathcal{E}, \mathcal{E}) \) of (6.3). The only point to check is that the cover-preserving functors to the left of this latter equivalence correspond to the regular-epimorphism-preserving ones to the right.

So suppose given a covering family \( \langle f, \mathcal{V} \rangle \) as in (6.8). We may form the image factorisation \( f = me: X \to \text{im } f \to Y \), and since by assumption \( \text{im } f \in \mathcal{V} \), we conclude that
\[
\langle f, \mathcal{V} \rangle = \langle (X, \mathcal{U}) \xrightarrow{[e]} (\text{im } f, \mathcal{V}|_{\text{im } f}) \xrightarrow{[m]} (Y, \mathcal{V}) \rangle_{\mathcal{U} \in \beta X, e!(\mathcal{U}) = \mathcal{V}|_{\text{im } f}}.
\]
Since \([m]\) is invertible in \( \mathcal{F}_\mathcal{E} \), this family will be sent to a jointly epimorphic one just when \( e!(\mathcal{V}|_{\text{im } f}) \) is; whence a functor \( A: \mathcal{F}_\mathcal{E} \to \mathcal{E} \) preserves all covers just when it preserves ones \( \langle f, \mathcal{V} \rangle \) as in (6.8) with \( f \) a regular epimorphism. This is equally to say that, for each \( f: X \to Y \) in \( \mathcal{E} \), the map to the left in:
\[
\sum_{\mathcal{U} \in \beta X \atop f_!(\mathcal{U}) = \mathcal{V}} A(X, \mathcal{U}) \to A(Y, \mathcal{V})
\]
\[
\sum_{\mathcal{U} \in \beta X} A(X, \mathcal{U}) \to \sum_{\mathcal{V} \in \beta X} A(Y, \mathcal{V})
\]
obtained by copairing the maps \( A([f]): A(X, \mathcal{U}) \to A(Y, \mathcal{V}) \) is an epimorphism in \( \mathcal{E} \). Summing these left-hand maps over all \( \mathcal{V} \in \beta Y \) and using infinite extensivity of \( \mathcal{E} \), this is equally the condition that, for each \( f: X \to Y \) in \( \mathcal{E} \), the map right above is an epimorphism. Since this map is the value at \( f \) of the functor \( f^*A: \mathcal{E} \to \mathcal{E} \) corresponding to \( A \) under (3.7), this completes the proof. \( \square \)

As before, chasing the identity geometric morphism \( \text{Sh}(\mathcal{F}_\mathcal{E}) \to \text{Sh}(\mathcal{F}_\mathcal{E}) \) through this proof shows that the universal pretopos map \( \eta: \mathcal{E} \to \text{Sh}(\mathcal{F}_\mathcal{E}) \) is the image under (3.7) of the composite \( \text{ay}: \mathcal{F}_\mathcal{E} \to \text{Sh}(\mathcal{F}_\mathcal{E}) \) of the Yoneda embedding and the sheafification functor. As such it is given by:
\[
\eta(X) = \sum_{\mathcal{U} \in \beta X} \text{ay}(X, \mathcal{U})
\].
Remark 42. We remarked above that the 2-functor $\mathcal{G}\text{Top}^{op} \to \text{Pretop}$ has a left biadjoint at every small pretopos given by the topos $\mathcal{S}h(C)$ for the topology of finite jointly epimorphic families. The toposes arising in this way are commonly known as coherent toposes; moreover, by [11, Theorem 3.11], the coherent topos associated to a small De Morgan pretopos is itself De Morgan. Given this, another way of seeing Theorem 41 is as giving an explicit construction of the locally connected coclosure [17] of any coherent De Morgan topos.

One may reasonably ask if we have a similar explicit construction upon dropping the qualifier “coherent”. The answer is yes, so long as we assume that every cardinal is smaller than some strongly compact cardinal. In this case, for any De Morgan Grothendieck topos $\mathcal{E}$, we can find a strongly compact cardinal $\kappa$ such that $\mathcal{E}$ is the free completion of a small De Morgan $\kappa$-ary pretopos—that is, a pretopos with pullback-stable $\kappa$-small coproducts. We can thus reduce the problem to constructing the locally connected classifying topos of a small $\kappa$-ary De Morgan pretopos; and we can do this by tracing through the definitions and results of this paper replacing everywhere finite coproducts by $\kappa$-complete ultrafilters—ones closed under $\kappa$-small intersections. The assumption of strong compactness of $\kappa$ is needed in the proofs of Proposition 38 and Theorem 41, where we are now required to extend the $\kappa$-complete filters (6.6) and (6.9) to $\kappa$-complete ultrafilters.

6.3. Relation to toposes of types. Our construction of a locally connected classifying topos by taking sheaves on a category of ultrafilters has many precedents in the literature. In these prior works, the category of ultrafilters may be replaced by a different category of filters, proper filters or prime filters, and moreover a different topology may be imposed, but in the end one forms a topos of sheaves in essentially the same manner; often, in recognition of the link with model theory, the nomenclature “topos of types” is employed. It is beyond the scope of this paper to attempt a detailed analysis of the relation between our work and this prior work, but we should at least discuss the main similarities and differences.

The earliest topos of types appears to be that in Joyal and Reyes’ [25]. Given a pretopos $\mathcal{C}$, a prime filter on $X \in \mathcal{C}$ is a prime filter in the distributive lattice $\text{Sub}_\mathcal{C}(X)$; these comprise the objects of a category $\mathcal{PF}_\mathcal{C}$ of prime filters in $\mathcal{C}$ defined similarly to $\mathcal{UF}_\mathcal{C}$. Endowing $\mathcal{PF}_\mathcal{C}$ with the obvious analogy of the topology of Proposition 40 yields [25]’s topos of existential types. No universal property is described, but the formula (3.6) appears on p.11 of ibid.

What is usually called the topos of types is that of Makkai’s [35]; it is a topos of sheaves on the same category $\mathcal{PF}_\mathcal{C}$, but for a different topology. Makkai exhibits it as the “classifying prime-generated topos for $\mathcal{p}$-models of $\mathcal{C}$. Here, a Grothendieck topos $\mathcal{E}$ is said to be prime-generated if each subobject lattice $\text{Sub}_\mathcal{E}(X)$ is a superalgebraic lattice\footnote{i.e., the free join-completion of a poset; this is not the original definition of prime-generation from [35], but an equivalent one from [2, §3].}, while a pretopos morphism $\mathcal{F}: \mathcal{C} \to \mathcal{E}$ into a prime-generated topos is said to be a $\mathcal{p}$-model if for every prime filter $\mathcal{p}$ on $\text{Sub}_\mathcal{C}(X)$ and every $f: X \to Y$ we have $\exists_f(\bigcap_{A \in \mathcal{C}} F A) = \bigcap_{A \in \mathcal{C}} F(\exists_f A)$ in $\text{Sub}_\mathcal{E}(FY)$. The
classifying property of the topos of types $\tau(\mathcal{C})$ is given by equivalences

\[(6.11) \quad \mathcal{P}\mathcal{G}\mathcal{T}\mathcal{op}(\mathcal{E}, \tau(\mathcal{C})) \simeq \mathcal{P}\mathcal{P}e\mathcal{t}\mathcal{op}(\mathcal{C}, \mathcal{E})\]

where to the left we have the category of geometric morphisms between prime-generated toposes whose inverse image functors preserve all intersections, and to the right we have the category of $\mathcal{p}$-models. In establishing this equivalence, the formula (3.6) again appears; see the bottom of p.164 of ibid. In model-theoretic terms, the condition of being a $\mathcal{p}$-model is a saturation condition; Makkai states this already in [35], and the point is followed up in [10], and exploited in, among other places, [38, 14].

The third main “topos of types” in the literature is Pitts’ topos of filters $\Phi(\mathcal{C})$ of a pretopos $\mathcal{C}$. Introduced in [39], this is the topos of sheaves on the category $\mathcal{F}_e\mathcal{C}$ of all—not necessarily prime—filters of subobjects, for the topology whose covers are the finite jointly epimorphic families. The universal property of $\Phi(\mathcal{C})$ was given in [34] by analogy with $\tau(\mathcal{C})$: it is the “classifying completely distributive topos for $f$-models of $\mathcal{C}$”. Here, a completely distributive topos is one whose subobject lattices are completely distributive, and an $f$-model is like a $\mathcal{p}$-model, but with arbitrary filters replacing prime ones.

We conclude this discussion by comparing the universal characterisation (6.11) of Makkai’s topos of types and our Theorem 41. To the left of the equivalence, our theorem replaces “prime-generated” by “locally connected” and moreover relaxes the condition of intersection-preservation on morphisms. What permits this relaxation is the fact that we only care about intersections of coproduct summands, and any inverse image functor between locally connected toposes preserves these. To the right of the equivalence, we drop the $\mathcal{p}$-model condition. This is to do with the fact that our choice of topology is analogous to Joyal and Reyes’ [25] rather than Makkai’s [35]. If one modifies Makkai’s topos of types to use Joyal and Reyes’ topology, then one can also drop the $\mathcal{p}$-model condition; however, the result is then no longer a prime-generated topos, and so it is unclear what an appropriate universal property would be. The final difference we note is that Makkai’s equivalence works for arbitrary pretoposes $\mathcal{C}$, while ours works only for De Morgan pretoposes; this extra condition seems to be necessary to ensure that the topos of sheaves we form is indeed locally connected.

Asides from these technical distinctions, we would raise one further point. In this paper, we have striven to make the constructions we give as unavoidable as possible. The category $\mathcal{U}\mathcal{F}_e\mathcal{C}$ is forced upon us once we are interested in finite-coproduct-preserving functors out of $\mathcal{C}$; adding finite-limit-preservation leads us to consider also flatness; and finally, once we add regular-epimorphism-preservation, we are led inevitably to the given topology on $\mathcal{U}\mathcal{F}_e\mathcal{C}$. Everything else is a matter of making the details match up$^2$. In future work, we intend to see whether our main results can be adapted to the prime filter setting, and if, on doing so, they provide a treatment of Makkai’s topos of types in the same spirit.

$^2$Though at this stage we have no satisfactory explanation for the requirement of De Morganess.
